

Package ‘paradox’

March 17, 2023

Type Package

Title Define and Work with Parameter Spaces for Complex Algorithms

Version 0.11.1

Description Define parameter spaces, constraints and dependencies for arbitrary algorithms, to program on such spaces. Also includes statistical designs and random samplers. Objects are implemented as 'R6' classes.

paradox: Define and Work with Parameter Spaces for Complex Algorithms

Description

Define parameter spaces, constraints and dependencies for arbitrary algorithms, to program on such spaces. Also includes statistical designs and random samplers. Objects are implemented as 'R6' classes.

assert_param

Assertions for Params and ParamSets

Description

Assertions for Params and ParamSets

Usage

```
assert_param(param, cl = "Param", no_untyped = FALSE, must_bounded = FALSE)

assert_param_set(
  param_set,
  cl = "Param",
  no_untyped = FALSE,
  must_bounded = FALSE,
  no_deps = FALSE
)
```

Arguments

param	(Param).
cl	(character()) Allowed subclasses.
no_untyped	(logical(1)) Are untyped Params allowed?
must_bounded	(logical(1)) Only bounded Params allowed?
param_set	(ParamSet).
no_deps	(logical(1)) Are dependencies allowed?

Value

The checked object, invisibly.

Condition	<i>Dependency Condition</i>
-----------	-----------------------------

Description

Condition object, to specify the condition in a dependency.

Currently implemented simple conditions

- CondEqual\$new(rhs)
Parent must be equal to rhs.
- CondAnyOf\$new(rhs)
Parent must be any value of rhs.

Public fields

type (character(1))
Name / type of the condition.
rhs (any)
Right-hand-side of the condition.

Methods**Public methods:**

- `Condition$new()`
- `Condition$test()`
- `Condition$as_string()`
- `Condition$format()`
- `Condition$print()`
- `Condition$clone()`

Method new(): Creates a new instance of this [R6](#) class.

Usage:

`Condition$new(type, rhs)`

Arguments:

type (character(1))
Name / type of the condition.
rhs (any)
Right-hand-side of the condition.

Method test(): Checks if condition is satisfied. Called on a vector of parent param values.

Usage:

`Condition$test(x)`

Arguments:

x (vector()).

Returns: logical(1).

Method as_string(): Conversion helper for print outputs.

Usage:

`Condition$as_string(lhs_chr = "x")`

Arguments:

lhs_chr (character(1))

Method format(): Helper for print outputs.

Usage:

`Condition$format(...)`

Arguments:

... (ignored).

Method `print()`: Printer.

Usage:

`Condition$print(...)`

Arguments:

... (ignored).

Method `clone()`: The objects of this class are cloneable with this method.

Usage:

`Condition$clone(deep = FALSE)`

Arguments:

`deep` Whether to make a deep clone.

`default_values`

Extract Parameter Default Values

Description

Extract parameter default values.

Usage

```
default_values(x, ...)
## S3 method for class 'ParamSet'
default_values(x, ...)
```

Arguments

<code>x</code>	(any)
	Object to extract default values from.
<code>...</code>	(any)
	Additional arguments.

Value

`list()`.

Design*Design of Configurations*

Description

A lightweight wrapper around a `ParamSet` and a `data.table::data.table()`, where the latter is a design of configurations produced from the former - e.g., by calling a `generate_design_grid()` or by sampling.

Public fields

`param_set` (`ParamSet`).
`data` (`data.table::data.table()`)
 Stored data.

Methods**Public methods:**

- `Design$new()`
- `Design$format()`
- `Design$print()`
- `Design$transpose()`
- `Design$clone()`

Method `new()`: Creates a new instance of this `R6` class.

Usage:

`Design$new(param_set, data, remove_dupl)`

Arguments:

`param_set` (`ParamSet`).
`data` (`data.table::data.table()`)
 Stored data.
`remove_dupl` (`logical(1)`)
 Remove duplicates?

Method `format()`: Helper for print outputs.

Usage:

`Design$format(...)`

Arguments:

... (ignored).

Method `print()`: Printer.

Usage:

`Design$print(...)`

Arguments:

... (ignored).

Method transpose(): Converts data into a list of lists of row-configurations, possibly removes NA entries of inactive parameter values due to unsatisfied dependencies, and possibly calls the trafo function of the [ParamSet](#).

Usage:

```
Design$transpose(filter_na = TRUE, trafo = TRUE)
```

Arguments:

filter_na (logical(1))

Should NA entries of inactive parameter values due to unsatisfied dependencies be removed?

trafo (logical(1))

Should the trafo function of the [ParamSet](#) be called?

Method clone(): The objects of this class are cloneable with this method.

Usage:

```
Design$clone(deep = FALSE)
```

Arguments:

deep Whether to make a deep clone.

Domain

Domain: Parameter Range without an Id

Description

A Domain object is a representation of a single dimension of a [ParamSet](#). Domain objects are used to construct [ParamSets](#), either through the [ps\(\)](#) short form, or through the [ParamSet\\$search_space\(\)](#) mechanism (see [to_tune\(\)](#)). Domain corresponds to a [Param](#) object, except it does not have an \$id, and it *does* have a trafo and dependencies (depends) associated with it. For each of the basic [Param](#) classes ([ParamInt](#), [ParamDbl](#), [ParamLgl](#), [ParamFct](#), and [ParamUty](#)) there is a function constructing a Domain object ([p_int\(\)](#), [p_dbl\(\)](#), [p_lgl\(\)](#), [p_fct\(\)](#), [p_uty\(\)](#)). They each have the same arguments as the corresponding [Param\\$new\(\)](#) function, except without the id argument, and with the the additional parameters trafo, and depends.

Domain objects are representations of parameter ranges and are intermediate objects to be used in short form constructions in [to_tune\(\)](#) and [ps\(\)](#). Because of their nature, they should not be modified by the user. The Domain object's internals are subject to change and should not be relied upon.

Usage

```
p_int(
  lower = -Inf,
  upper = Inf,
  special_vals = list(),
```

```
default = NO_DEF,
tags = character(),
depends = NULL,
trafo = NULL,
logscale = FALSE
)

p_dbl(
  lower = -Inf,
  upper = Inf,
  special_vals = list(),
  default = NO_DEF,
  tags = character(),
  tolerance = sqrt(.Machine$double.eps),
  depends = NULL,
  trafo = NULL,
  logscale = FALSE
)

p_uty(
  default = NO_DEF,
  tags = character(),
  custom_check = NULL,
  depends = NULL,
  trafo = NULL
)

p_lgl(
  special_vals = list(),
  default = NO_DEF,
  tags = character(),
  depends = NULL,
  trafo = NULL
)

p_fct(
  levels,
  special_vals = list(),
  default = NO_DEF,
  tags = character(),
  depends = NULL,
  trafo = NULL
)
```

Arguments

lower (numeric(1))
Lower bound, can be -Inf.

upper	(numeric(1)) Upper bound can be +Inf.
special_vals	(list()) Arbitrary special values this parameter is allowed to take, to make it feasible. This allows extending the domain of the parameter. Note that these values are only used in feasibility checks, neither in generating designs nor sampling.
default	(any) Default value. Can be from the domain of the parameter or an element of <code>special_vals</code> . Has value <code>NO_DEF</code> if no default exists. NULL can be a valid default. The value has no effect on <code>ParamSet\$values</code> or the behavior of <code>ParamSet\$check()</code> , <code>\$test()</code> or <code>\$assert()</code> . The default is intended to be used for documentation purposes. ‘
tags	(character()) Arbitrary tags to group and subset parameters. Some tags serve a special purpose: <ul style="list-style-type: none"> “required” implies that the parameters has to be given when setting values in <code>ParamSet</code>.
depends	(call expression) An expression indicating a requirement for the parameter that will be constructed from this. Can be given as an expression (using <code>quote()</code>), or the expression can be entered directly and will be parsed using NSE (see examples). The expression may be of the form <code><Param> == <value></code> or <code><Param> %in% <values></code> , which will result in dependencies according to <code>ParamSet\$add_dep(on = "<Param>", cond = CondEqual\$new(<value>))</code> or <code>ParamSet\$add_dep(on = "<Param>", cond = CondAnyOf\$new(<values>))</code> , respectively (see <code>CondEqual</code> , <code>CondAnyOf</code>). The expression may also contain multiple conditions separated by <code>&&</code> .
trafo	(function) Single argument function performing the transformation of a parameter. When the <code>Domain</code> is used to construct a <code>ParamSet</code> , this transformation will be applied to the corresponding parameter as part of the <code>\$trafo</code> function. Note that the trafo is <i>not</i> inherited by <code>TuneTokens!</code> Defining a parameter with e.g. <code>p_dbl(..., trafo = ...)</code> will <i>not</i> automatically give the <code>to_tune()</code> assigned to it a transformation. <code>trafo</code> only makes sense for <code>ParamSets</code> that get used as search spaces for optimization or tuning, it is not useful when defining domains or hyperparameter ranges of learning algorithms, because these do not use <code>trafos</code> .
logscale	(logical(1)) Put numeric domains on a log scale. Default FALSE. Log-scale Domains represent parameter ranges where lower and upper bounds are logarithmized, and where a trafo is added that exponentiates sampled values to the original scale. This is <i>not</i> the same as setting <code>trafo = exp</code> , because <code>logscale = TRUE</code> will handle parameter bounds internally: a <code>p_dbl(1, 10, logscale = TRUE)</code> results in a <code>ParamDbl</code> that has lower bound 0, upper bound <code>log(10)</code> , and uses <code>exp</code> transformation on these. Therefore, the given bounds represent the bounds <i>after</i> the transformation. (see examples). <code>p_int()</code> with <code>logscale = TRUE</code> results in a <code>ParamDbl</code> , not a <code>ParamInt</code> , but

with bounds $\log(\max(lower, 0.5)) \dots \log(upper + 1)$ and a trafo similar to "as.integer(exp(x))" (with additional bounds correction). The lower bound is lifted to 0.5 if lower 0 to handle the lower == 0 case. The upper bound is increased to $\log(upper + 1)$ because the trafo would otherwise almost never generate a value of upper.

When logscale is TRUE, then upper bounds may be infinite, but lower bounds should be greater than 0 for p_dbl() or greater or equal 0 for p_int().

Note that "logscale" is *not* inherited by [TuneTokens](#)! Defining a parameter with p_dbl(... logscale = TRUE) will *not* automatically give the to_tune() assigned to it log-scale. logscale only makes sense for [ParamSets](#) that get used as search spaces for optimization or tuning, it is not useful when defining domains or hyperparameter ranges of learning algorithms, because these do not use trafos.

logscale happens on a natural ($e == 2.718282\dots$) basis. Be aware that using a different base ($\log10()/10^x$, $\log2()/2^x$) is completely equivalent and does not change the values being sampled after transformation.

tolerance	(numeric(1))
	Initializes the \$tolerance field that determines the
custom_check	(function())
	Custom function to check the feasibility. Function which checks the input. Must return 'TRUE' if the input is valid and a character(1) with the error message otherwise. This function should <i>not</i> throw an error. Defaults to NULL, which means that no check is performed.
levels	(character atomic list)
	Allowed categorical values of the parameter. If this is not a character, then a trafo is generated that converts the names (if not given: as.character() of the values) of the levels argument to the values. This trafo is then performed <i>before</i> the function given as the trafo argument.

Details

The p_fct function admits a levels argument that goes beyond the levels accepted by [ParamFct\\$new\(\)](#). Instead of a character vector, any atomic vector or list (optionally named) may be given. (If the value is a list that is not named, the names are inferred using as.character() on the values.) The resulting Domain will correspond to a range of values given by the names of the levels argument with a trafo that maps the character names to the arbitrary values of the levels argument.

Value

A Domain object.

See Also

Other ParamSet construction helpers: [ps\(\)](#), [to_tune\(\)](#)

Examples

```
params = ps(
  unbounded_integer = p_int(),
```

```

bounded_double = p_dbl(0, 10),
half_bounded_integer = p_dbl(1),
half_bounded_double = p_dbl(upper = 1),
double_with_trafo = p_dbl(-1, 1, trafo = exp),
extra_double = p_dbl(0, 1, special_vals = list("xxx"), tags = "tagged"),
factor_param = p_fct(c("a", "b", "c")),
factor_param_with_implicit_trafo = p_fct(list(a = 1, b = 2, c = list()))
)
print(params)

params$trafo(list(
  bounded_double = 1,
  double_with_trafo = 1,
  factor_param = "c",
  factor_param_with_implicit_trafo = "c"
))
# logscale:
params = ps(x = p_dbl(1, 100, logscale = TRUE))

# The ParamSet has bounds log(1) .. log(100):
print(params)

# When generating a equidistant grid, it is equidistant within log values
grid = generate_design_grid(params, 3)
print(grid)

# But the values are on a log scale with desired bounds after trafo
print(grid$transpose())

# Integer parameters with logscale are `ParamDbl`'s pre-trafo
params = ps(x = p_int(0, 10, logscale = TRUE))
print(params)

grid = generate_design_grid(params, 4)
print(grid)

# ... but get transformed to integers.
print(grid$transpose())

```

generate_design_grid *Generate a Grid Design*

Description

Generate a grid with a specified resolution in the parameter space. The resolution for categorical parameters is ignored, these parameters always produce a grid over all their valid levels. For number params the endpoints of the params are always included in the grid.

Usage

```
generate_design_grid(param_set, resolution = NULL, param_resolutions = NULL)
```

Arguments

param_set ([ParamSet](#)).
 resolution (integer(1))
 Global resolution for all [Params](#).
 param_resolutions
 (named integer())
 Resolution per [Param](#), named by parameter ID.

Value

[Design](#).

See Also

Other generate_design: [generate_design_lhs\(\)](#), [generate_design_random\(\)](#), [generate_design_sobol\(\)](#)

Examples

```
ps = ParamSet$new(list(  

  ParamDbl$new("ratio", lower = 0, upper = 1),  

  ParamFct$new("letters", levels = letters[1:3])  

))  

generate_design_grid(ps, 10)
```

generate_design_lhs *Generate a Space-Filling LHS Design*

Description

Generate a space-filling design using Latin hypercube sampling. Dependent parameters whose constraints are unsatisfied generate NA entries in their respective columns.

Usage

```
generate_design_lhs(param_set, n, lhs_fun = NULL)
```

Arguments

param_set ([ParamSet](#)).
 n (integer(1))
 Number of points to sample.
 lhs_fun (function(n, k))
 Function to use to generate a LHS sample, with n samples and k values per
 param. LHS functions are implemented in package [lhs](#), default is to use [lhs::maximinLHS\(\)](#).

Value

`Design.`

See Also

Other generate_design: [generate_design_grid\(\)](#), [generate_design_random\(\)](#), [generate_design_sobol\(\)](#)

Examples

```
ps = ParamSet$new(list(
  ParamDbl$new("ratio", lower = 0, upper = 1),
  ParamFct$new("letters", levels = letters[1:3])
))

if (requireNamespace("lhs", quietly = TRUE)) {
  generate_design_lhs(ps, 10)
}
```

generate_design_random

Generate a Random Design

Description

Generates a design with randomly drawn points. Internally uses [SamplerUnif](#), hence, also works for [ParamSets](#) with dependencies. If dependencies do not hold, values are set to NA in the resulting data.table.

Usage

```
generate_design_random(param_set, n)
```

Arguments

param_set	(ParamSet).
n	(integer(1))
	Number of points to draw randomly.

Value

`Design.`

See Also

Other generate_design: [generate_design_grid\(\)](#), [generate_design_lhs\(\)](#), [generate_design_sobol\(\)](#)

Examples

```
ps = ParamSet$new(list(
  ParamDbl$new("ratio", lower = 0, upper = 1),
  ParamFct$new("letters", levels = letters[1:3])
))
generate_design_random(ps, 10)
```

`generate_design_sobol` *Generate a Space-Filling Sobol Sequence Design*

Description

Generate a space-filling design using a Sobol sequence. Dependent parameters whose constraints are unsatisfied generate NA entries in their respective columns.

Uses [spacefillr::generate_sobol_set](#).

Note that non determinism is achieved by sampling the seed argument via `sample(.Machine$integer.max, size = 1L)`.

Usage

```
generate_design_sobol(param_set, n)
```

Arguments

param_set	(ParamSet).
n	(<code>integer(1)</code>) Number of points to sample.

Value

[Design](#).

See Also

Other generate_design: [generate_design_grid\(\)](#), [generate_design_lhs\(\)](#), [generate_design_random\(\)](#)

Examples

```
ps = ParamSet$new(list(
  ParamDbl$new("ratio", lower = 0, upper = 1),
  ParamFct$new("letters", levels = letters[1:3])
))

if (requireNamespace("spacefillr", quietly = TRUE)) {
  generate_design_sobol(ps, 10)
}
```

NO_DEF	<i>Extra data type for "no default value"</i>
--------	---

Description

Special new data type for no-default. Not often needed by the end-user, mainly internal.

- NoDefault: R6 factory.
- NO_DEF: R6 Singleton object for type, used in [Param](#).
- `is_nodefault()`: Is an object of type 'no default'?

Param	<i>Param Class</i>
-------	--------------------

Description

This is the abstract base class for parameter objects like [ParamDbl](#) and [ParamFct](#).

S3 methods

- `as.data.table()`
[Param](#) -> [data.table::data.table\(\)](#)
 Converts param to [data.table::data.table\(\)](#) with 1 row. See [ParamSet](#).

Public fields

```

id (character(1))
  Identifier of the object.

description (character(1))
  String to describe this parameter. Used, for example, in mlr3misc::rd\_info\(\) to automatically generate documentation for parameter sets.

special_vals (list())
  Arbitrary special values this parameter is allowed to take.

default (any)
  Default value.

tags (character())
  Arbitrary tags to group and subset parameters.

```

Active bindings

```
class (character(1))
  R6 class name. Read-only.

is_number (logical(1))
  TRUE if the parameter is of type "dbl" or "int".

is_categ (logical(1))
  TRUE if the parameter is of type "fct" or "lg1".

has_default (logical(1))
  Is there a default value?
```

Methods

Public methods:

- [Param\\$new\(\)](#)
- [Param\\$check\(\)](#)
- [Param\\$assert\(\)](#)
- [Param\\$test\(\)](#)
- [Param\\$rep\(\)](#)
- [Param\\$format\(\)](#)
- [Param\\$print\(\)](#)
- [Param\\$qunif\(\)](#)
- [Param\\$convert\(\)](#)
- [Param\\$clone\(\)](#)

Method new(): Creates a new instance of this [R6](#) class.

Note that this object is typically constructed via derived classes, e.g., [ParamDbl](#).

Usage:

```
Param$new(id, special_vals, default, tags)
```

Arguments:

`id` (character(1))
 Identifier of the object.

`special_vals` (list())
 Arbitrary special values this parameter is allowed to take, to make it feasible. This allows extending the domain of the parameter. Note that these values are only used in feasibility checks, neither in generating designs nor sampling.

`default` (any)
 Default value. Can be from the domain of the parameter or an element of `special_vals`. Has value [NO_DEF](#) if no default exists. NULL can be a valid default. The value has no effect on `ParamSet$values` or the behavior of `ParamSet$check()`, `$test()` or `$assert()`. The default is intended to be used for documentation purposes. ‘

`tags` (character())
 Arbitrary tags to group and subset parameters. Some tags serve a special purpose:

- "required" implies that the parameters has to be given when setting values in [ParamSet](#).

Method `check()`: **checkmate**-like check-function. Take a value from the domain of the parameter, and check if it is feasible. A value is feasible if it is of the same `storage_type`, inside of the bounds or element of `special_vals`.

Usage:

```
Param$check(x)
```

Arguments:

`x` (any).

Returns: If successful TRUE, if not a string with the error message.

Method `assert()`: **checkmate**-like assert-function. Take a value from the domain of the parameter, and assert if it is feasible. A value is feasible if it is of the same `storage_type`, inside of the bounds or element of `special_vals`.

Usage:

```
Param$assert(x)
```

Arguments:

`x` (any).

Returns: If successful `x` invisibly, if not an exception is raised.

Method `test()`: **checkmate**-like test-function. Take a value from the domain of the parameter, and test if it is feasible. A value is feasible if it is of the same `storage_type`, inside of the bounds or element of `special_vals`.

Usage:

```
Param$test(x)
```

Arguments:

`x` (any).

Returns: If successful TRUE, if not FALSE.

Method `rep()`: Repeats this parameter n-times (by cloning). Each parameter is named "[id]`rep[k]`" and gets the additional tag "[id]_rep".

Usage:

```
Param$rep(n)
```

Arguments:

`n` (integer(1)).

Returns: [ParamSet](#).

Method `format()`: Helper for print outputs.

Usage:

```
Param=format(...)
```

Arguments:

... (ignored).

Method print(): Printer.

Usage:

Param\$print(

```
  ...,
  hide_cols = c("nlevels", "is_bounded", "special_vals", "tags", "storage_type")
)
```

Arguments:

... (ignored).

hide_cols (character())

Which fields should not be printed? Default is "nlevels", "is_bounded", "special_vals", "tags", and "storage_type".

Method qunif(): Takes values from [0,1] and maps them, regularly distributed, to the domain of the parameter. Think of: quantile function or the use case to map a uniform-[0,1] random variable into a uniform sample from this param.

Usage:

Param\$qunif(x)

Arguments:

x (numeric(1)).

Returns: Value of the domain of the parameter.

Method convert(): Converts a value to the closest valid param. Only for values that pass \$check() and mostly used internally.

Usage:

Param\$convert(x)

Arguments:

x (any).

Returns: x converted to a valid type for the Param.

Method clone(): The objects of this class are cloneable with this method.

Usage:

Param\$clone(deep = FALSE)

Arguments:

deep Whether to make a deep clone.

See Also

Other Params: [ParamDb1](#), [ParamFct](#), [ParamInt](#), [ParamLgl](#), [ParamUty](#)

ParamDbl*Numerical Parameter*

Description

A [Param](#) to describe real-valued parameters.

Super class

[paradox::Param](#) -> [ParamDbl](#)

Public fields

`lower` (`numeric(1)`)

Lower bound. Always NA for [ParamFct](#), [ParamLgl](#) and [ParamUty](#).

`upper` (`numeric(1)`)

Upper bound. Always NA for [ParamFct](#), [ParamLgl](#) and [ParamUty](#).

`tolerance` (`numeric(1)`)

tolerance of values to accept beyond `$lower` and `$upper`. Used both for relative and absolute tolerance.

Active bindings

`levels` (`character()` | `NULL`)

Set of allowed levels. Always `NULL` for [ParamDbl](#), [ParamInt](#) and [ParamUty](#). Always `c(TRUE, FALSE)` for [ParamLgl](#).

`nlevels` (`integer(1)` | `Inf`)

Number of categorical levels. Always `Inf` for [ParamDbl](#) and [ParamUty](#). The number of integers in the range `[lower, upper]`, or `Inf` if unbounded for [ParamInt](#). Always 2 for [ParamLgl](#).

`is_bounded` (`logical(1)`)

Are the bounds finite? Always TRUE for [ParamFct](#) and [ParamLgl](#). Always FALSE for [ParamUty](#).

`storage_type` (`character(1)`)

Data type when values of this parameter are stored in a data table or sampled. Always "numeric" for [ParamDbl](#). Always "character" for [ParamFct](#). Always "integer" for [ParamInt](#). Always "logical" for [ParamLgl](#). Always "list" for [ParamUty](#).

Methods**Public methods:**

- [ParamDbl\\$new\(\)](#)
- [ParamDbl\\$convert\(\)](#)
- [ParamDbl\\$clone\(\)](#)

Method new(): Creates a new instance of this [R6](#) class.

Usage:

```
ParamDb1$new(
  id,
  lower = -Inf,
  upper = Inf,
  special_vals = list(),
  default = NO_DEF,
  tags = character(),
  tolerance = sqrt(.Machine$double.eps)
)
```

Arguments:

- id (character(1))

Identifier of the object.
- lower (numeric(1))

Lower bound, can be -Inf.
- upper (numeric(1))

Upper bound can be +Inf.
- special_vals (list())

Arbitrary special values this parameter is allowed to take, to make it feasible. This allows extending the domain of the parameter. Note that these values are only used in feasibility checks, neither in generating designs nor sampling.
- default (any)

Default value. Can be from the domain of the parameter or an element of special_vals. Has value NO_DEF if no default exists. NULL can be a valid default. The value has no effect on ParamSet\$values or the behavior of ParamSet\$check(), \$test() or \$assert(). The default is intended to be used for documentation purposes. ‘
- tags (character())

Arbitrary tags to group and subset parameters. Some tags serve a special purpose:

 - “required” implies that the parameters has to be given when setting values in [ParamSet](#).

tolerance (numeric(1))
 Initializes the \$tolerance field that determines the

Method convert(): Restrict the value to within the allowed range. This works in conjunction with \$tolerance, which accepts values slightly out of this range.

Usage:

```
ParamDb1$convert(x)
```

Arguments:
 x (numeric(1))

Value to convert.

Method clone(): The objects of this class are cloneable with this method.

Usage:

```
ParamDb1$clone(deep = FALSE)
```

Arguments:
 deep Whether to make a deep clone.

Note

The upper and lower bounds in `$check()` are expanded by `sqrt(.Machine$double.eps)` to prevent errors due to the precision of double values.

Other Params: [ParamFct](#), [ParamInt](#), [ParamLgl](#), [ParamUty](#), [Param](#)

Examples

```
ParamDbl$new("ratio", lower = 0, upper = 1, default = 0.5)
```

[ParamFct](#)

Factor Parameter

Description

A [Param](#) to describe categorical (factor) parameters.

Super class

[paradox::Param](#) -> [ParamFct](#)

Public fields

`levels` (character() | NULL)

Set of allowed levels. Always NULL for [ParamDbl](#), [ParamInt](#) and [ParamUty](#). Always `c(TRUE, FALSE)` for [ParamLgl](#).

Active bindings

`lower` (numeric(1))

Lower bound. Always NA for [ParamFct](#), [ParamLgl](#) and [ParamUty](#).

`upper` (numeric(1))

Upper bound. Always NA for [ParamFct](#), [ParamLgl](#) and [ParamUty](#).

`nlevels` (integer(1) | Inf)

Number of categorical levels. Always Inf for [ParamDbl](#) and [ParamUty](#). The number of integers in the range [lower, upper], or Inf if unbounded for [ParamInt](#). Always 2 for [ParamLgl](#).

`is_bounded` (logical(1))

Are the bounds finite? Always TRUE for [ParamFct](#) and [ParamLgl](#). Always FALSE for [ParamUty](#).

`storage_type` (character(1))

Data type when values of this parameter are stored in a data table or sampled. Always "numeric" for [ParamDbl](#). Always "character" for [ParamFct](#). Always "integer" for [ParamInt](#). Always "logical" for [ParamLgl](#). Always "list" for [ParamUty](#).

Methods

Public methods:

- `ParamFct$new()`
- `ParamFct$clone()`

Method new(): Creates a new instance of this [R6](#) class.

Usage:

```
ParamFct$new(
  id,
  levels,
  special_vals = list(),
  default = NO_DEF,
  tags = character()
)
```

Arguments:

`id` (character(1))
 Identifier of the object.
`levels` (character())
 Set of allowed levels.
`special_vals` (list())

Arbitrary special values this parameter is allowed to take, to make it feasible. This allows extending the domain of the parameter. Note that these values are only used in feasibility checks, neither in generating designs nor sampling.

`default` (any)
 Default value. Can be from the domain of the parameter or an element of `special_vals`. Has value `NO_DEF` if no default exists. NULL can be a valid default. The value has no effect on `ParamSet$values` or the behavior of `ParamSet$check()`, `$test()` or `$assert()`. The default is intended to be used for documentation purposes. ‘

`tags` (character())
 Arbitrary tags to group and subset parameters. Some tags serve a special purpose:

- “required” implies that the parameters has to be given when setting values in [ParamSet](#).

Method clone(): The objects of this class are cloneable with this method.

Usage:

```
ParamFct$clone(deep = FALSE)
```

Arguments:

`deep` Whether to make a deep clone.

See Also

Other Params: [ParamDbl](#), [ParamInt](#), [ParamLgl](#), [ParamUty](#), [Param](#)

Examples

```
ParamFct$new("f", levels = letters[1:3])
```

<code>ParamInt</code>	<i>Integer Parameter</i>
-----------------------	--------------------------

Description

A [Param](#) to describe integer parameters.

Methods

See [Param](#).

Super class

`paradox::Param` -> `ParamInt`

Public fields

`lower` (`numeric(1)`)

Lower bound. Always NA for [ParamFct](#), [ParamLgl](#) and [ParamUty](#).

`upper` (`numeric(1)`)

Upper bound. Always NA for [ParamFct](#), [ParamLgl](#) and [ParamUty](#).

Active bindings

`levels` (`character()` | `NULL`)

Set of allowed levels. Always `NULL` for [ParamDbl](#), [ParamInt](#) and [ParamUty](#). Always `c(TRUE, FALSE)` for [ParamLgl](#).

`nlevels` (`integer(1)` | `Inf`)

Number of categorical levels. Always `Inf` for [ParamDbl](#) and [ParamUty](#). The number of integers in the range [`lower`, `upper`], or `Inf` if unbounded for [ParamInt](#). Always 2 for [ParamLgl](#).

`is_bounded` (`logical(1)`)

Are the bounds finite? Always TRUE for [ParamFct](#) and [ParamLgl](#). Always FALSE for [ParamUty](#).

`storage_type` (`character(1)`)

Data type when values of this parameter are stored in a data table or sampled. Always "numeric" for [ParamDbl](#). Always "character" for [ParamFct](#). Always "integer" for [ParamInt](#). Always "logical" for [ParamLgl](#). Always "list" for [ParamUty](#).

Methods

Public methods:

- `ParamInt$new()`
- `ParamInt$convert()`
- `ParamInt$clone()`

Method new(): Creates a new instance of this [R6](#) class.

Usage:

```
ParamInt$new(
  id,
  lower = -Inf,
  upper = Inf,
  special_vals = list(),
  default = NO_DEF,
  tags = character()
)
```

Arguments:

`id` (`character(1)`)
Identifier of the object.

`lower` (`numeric(1)`)
Lower bound, can be `-Inf`.

`upper` (`numeric(1)`)
Upper bound can be `+Inf`.

`special_vals` (`list()`)
Arbitrary special values this parameter is allowed to take, to make it feasible. This allows extending the domain of the parameter. Note that these values are only used in feasibility checks, neither in generating designs nor sampling.

`default` (`any`)
Default value. Can be from the domain of the parameter or an element of `special_vals`. Has value `NO_DEF` if no default exists. `NULL` can be a valid default. The value has no effect on `ParamSet$values` or the behavior of `ParamSet$check()`, `$test()` or `$assert()`. The `default` is intended to be used for documentation purposes.

`tags` (`character()`)
Arbitrary tags to group and subset parameters. Some tags serve a special purpose:

- “required” implies that the parameters has to be given when setting values in [ParamSet](#).

Method convert(): Converts a value to an integer.

Usage:

```
ParamInt$convert(x)
```

Arguments:

`x` (`numeric(1)`)
Value to convert.

Method clone(): The objects of this class are cloneable with this method.

Usage:

```
ParamInt$clone(deep = FALSE)
```

Arguments:

`deep` Whether to make a deep clone.

levels (named list())
List of character vectors of allowed categorical values of contained parameters. NULL if the parameter is not categorical. Named with parameter IDs.

nlevels (named integer())
Number of categorical levels per parameter, Inf for double parameters or unbounded integer parameters. Named with param IDs.

is_bounded (named logical())
Do all parameters have finite bounds? Named with parameter IDs.

special_vals (named list() of list())
Special values for all parameters. Named with parameter IDs.

default (named list())
Default values of all parameters. If no default exists, element is not present. Named with parameter IDs.

tags (named list() of character())
Can be used to group and subset parameters. Named with parameter IDs.

storage_type (character())
Data types of parameters when stored in tables. Named with parameter IDs.

is_number (named logical())
Position is TRUE for **ParamDbl** and **ParamInt**. Named with parameter IDs.

is_categ (named logical())
Position is TRUE for **ParamFct** and **ParamLgl**. Named with parameter IDs.

all_numeric (logical(1))
Is TRUE if all parameters are **ParamDbl** or **ParamInt**.

all_categorical (logical(1))
Is TRUE if all parameters are **ParamFct** and **ParamLgl**.

trafo (function(x, param_set))
Transformation function. Settable. User has to pass a function(x, param_set), of the form (named list(), **ParamSet**) -> named list().
The function is responsible to transform a feasible configuration into another encoding, before potentially evaluating the configuration with the target algorithm. For the output, not many things have to hold. It needs to have unique names, and the target algorithm has to accept the configuration. For convenience, the self-paramset is also passed in, if you need some info from it (e.g. tags). Is NULL by default, and you can set it to NULL to switch the transformation off.

has_trafo (logical(1))
Has the set a **trafo** function?

values (named list())
Currently set / fixed parameter values. Settable, and feasibility of values will be checked when you set them. You do not have to set values for all parameters, but only for a subset. When you set values, all previously set values will be unset / removed.

has_deps (logical(1))
Has the set parameter dependencies?

Methods

Public methods:

- `ParamSet$new()`
- `ParamSet$add()`
- `ParamSet$ids()`
- `ParamSet$get_values()`
- `ParamSet$set_values()`
- `ParamSet$subset()`
- `ParamSet$search_space()`
- `ParamSet$check()`
- `ParamSet$test()`
- `ParamSet$assert()`
- `ParamSet$check_dt()`
- `ParamSet$test_dt()`
- `ParamSet$assert_dt()`
- `ParamSet$add_dep()`
- `ParamSet$format()`
- `ParamSet$print()`
- `ParamSet$clone()`

Method `new()`: Creates a new instance of this [R6](#) class.

Usage:

```
ParamSet$new(params = named_list())
```

Arguments:

`params` (`list()`)

List of [Param](#), named with their respective ID. Parameters are cloned.

Method `add()`: Adds a single param or another set to this set, all params are cloned.

Usage:

```
ParamSet$add(p)
```

Arguments:

`p` ([Param](#) | [ParamSet](#)).

Method `ids()`: Retrieves IDs of contained parameters based on some filter criteria selections, NULL means no restriction. Only returns IDs of parameters that satisfy all conditions.

Usage:

```
ParamSet$ids(class = NULL, is_bounded = NULL, tags = NULL)
```

Arguments:

`class` (`character()`).

`is_bounded` (`logical(1)`).

`tags` (`character()`).

Returns: `character()`.

Method `get_values()`: Retrieves parameter values based on some selections, NULL means no restriction and is equivalent to `$values`. Only returns values of parameters that satisfy all conditions.

Usage:

```
ParamSet$get_values(
  class = NULL,
  is_bounded = NULL,
  tags = NULL,
  type = "with_token",
  check_required = TRUE
)
```

Arguments:

- `class` (character()).
- `is_bounded` (logical(1)).
- `tags` (character()).
- `type` (character(1))

Return values `with_token`, `without_token` or `only_token`?

`check_required` (logical(1))

Check if all required parameters are set?

Returns: Named list().

Method `set_values()`: Allows to modify (and overwrite) or replace the parameter values. Per default already set values are being kept unless new values are being provided.

Usage:

```
ParamSet$set_values(..., .values = list(), .insert = TRUE)
```

Arguments:

- `...` (any)

Named parameter values.

- `.values` (named list())

Named list with parameter values. Names must not already appear in

- `.insert` (logical(1))

Whether to insert the values (old values are being kept, if not overwritten), or to replace all values. Default is TRUE.

Method `subset()`: Changes the current set to the set of passed IDs.

Usage:

```
ParamSet$subset(ids)
```

Arguments:

- `ids` (character()).

Method `search_space()`: Construct a `ParamSet` to tune over. Constructed from `TuneToken` in `$values`, see `to_tune()`.

Usage:

```
ParamSet$search_space(values = self$values)
```

Arguments:

`values` (named list): optional named list of [TuneToken](#) objects to convert, in place of `$values`.

Method `check()`: **checkmate**-like check-function. Takes a named list. A point x is feasible, if it configures a subset of params, all individual param constraints are satisfied and all dependencies are satisfied. Params for which dependencies are not satisfied should not be part of x.

Usage:

```
ParamSet$check(xs)
```

Arguments:

`xs` (named list()).

Returns: If successful TRUE, if not a string with the error message.

Method `test()`: **checkmate**-like test-function. Takes a named list. A point x is feasible, if it configures a subset of params, all individual param constraints are satisfied and all dependencies are satisfied. Params for which dependencies are not satisfied should not be part of x.

Usage:

```
ParamSet$test(xs)
```

Arguments:

`xs` (named list()).

Returns: If successful TRUE, if not FALSE.

Method `assert()`: **checkmate**-like assert-function. Takes a named list. A point x is feasible, if it configures a subset of params, all individual param constraints are satisfied and all dependencies are satisfied. Params for which dependencies are not satisfied should not be part of x.

Usage:

```
ParamSet$assert(xs, .var.name = vname(xs))
```

Arguments:

`xs` (named list()).

`.var.name` (character(1))

Name of the checked object to print in error messages.

Defaults to the heuristic implemented in [vname](#).

Returns: If successful xs invisibly, if not an error message.

Method `check_dt()`: **checkmate**-like check-function. Takes a [data.table::data.table](#) where rows are points and columns are parameters. A point x is feasible, if it configures a subset of params, all individual param constraints are satisfied and all dependencies are satisfied. Params for which dependencies are not satisfied should be set to NA in xdt.

Usage:

```
ParamSet$check_dt(xdt)
```

Arguments:

`xdt` ([data.table::data.table](#) | [data.frame](#)()).

Returns: If successful TRUE, if not a string with the error message.

Method `test_dt()`: **checkmate**-like test-function (s. `$check_dt()`).

Usage:

`ParamSet$test_dt(xdt)`

Arguments:

`xdt` (`data.table::data.table`).

Returns: If successful TRUE, if not FALSE.

Method `assert_dt()`: **checkmate**-like assert-function (s. `$check_dt()`).

Usage:

`ParamSet$assert_dt(xdt, .var.name = vname(xdt))`

Arguments:

`xdt` (`data.table::data.table`).

`.var.name` (character(1))

Name of the checked object to print in error messages.

Defaults to the heuristic implemented in `vname`.

Returns: If successful xs invisibly, if not an error message.

Method `add_dep()`: Adds a dependency to this set, so that param id now depends on param on.

Usage:

`ParamSet$add_dep(id, on, cond)`

Arguments:

`id` (character(1)).

`on` (character(1)).

`cond` (`Condition`).

Method `format()`: Helper for print outputs.

Usage:

`ParamSet/format(...)`

Arguments:

... (ignored).

Method `print()`: Printer.

Usage:

`ParamSet/print(`

...,

`hide_cols = c("levels", "is_bounded", "special_vals", "tags", "storage_type")`
)

Arguments:

... (ignored).

`hide_cols` (character())

Which fields should not be printed? Default is "levels", "is_bounded", "special_vals", "tags", and "storage_type".

Method `clone()`: The objects of this class are cloneable with this method.

Usage:

`ParamSet$clone(deep = FALSE)`

Arguments:

`deep` Whether to make a deep clone.

Examples

```
ps = ParamSet$new(
  params = list(
    d = ParamDbl$new("d", lower = -5, upper = 5, default = 0),
    f = ParamFct$new("f", levels = letters[1:3])
  )
)

ps$trafo = function(x, param_set) {
  x$d = 2^x$d
  return(x)
}

ps$add(ParamInt$new("i", lower = 0L, upper = 16L))

ps$check(list(d = 2.1, f = "a", i = 3L))
```

Description

A collection of multiple [ParamSet](#) objects.

- The collection is basically a light-weight wrapper / container around references to multiple sets.
- In order to ensure unique param names, every param in the collection is referred to with "`<set_id>.<param_id>`". Parameters from ParamSets with empty (i.e. "") `$set_id` are referenced directly. Multiple ParamSets with `$set_id` "" can be combined, but their parameter names must be unique.
- Operation `subset` is currently not allowed.
- Operation `add` currently only works when adding complete sets not single params.
- When you either ask for '`values`' or set them, the operation is delegated to the individual, contained param set references. The collection itself does not maintain a `values` state. This also implies that if you directly change values in one of the referenced sets, this change is reflected in the collection.
- Dependencies: It is possible to currently handle dependencies
 - regarding parameters inside of the same set - in this case simply add the dependency to the set, best before adding the set to the collection

- across sets, where a param from one set depends on the state of a param from another set
 - in this case add call add_dep on the collection.

If you call deps on the collection, you are returned a complete table of dependencies, from sets and across sets.

Super class

`paradox::ParamSet -> ParamSetCollection`

Active bindings

`params` (named list())

List of `Param`, named with their respective ID.

`params_unid` (named list())

List of `Param`, named with their true ID. However, this field has the `Param`'s \$id value set to a potentially invalid value. This active binding should only be used internally.

`deps` (`data.table::data.table()`)

Table has cols id (character(1)) and on (character(1)) and cond (`Condition`). Lists all (direct) dependency parents of a param, through parameter IDs. Internally created by a call to add_dep. Settable, if you want to remove dependencies or perform other changes.

`values` (named list())

Currently set / fixed parameter values. Settable, and feasibility of values will be checked when you set them. You do not have to set values for all parameters, but only for a subset. When you set values, all previously set values will be unset / removed.

Methods

Public methods:

- `ParamSetCollection$new()`
- `ParamSetCollection$add()`
- `ParamSetCollection$remove_sets()`
- `ParamSetCollection$subset()`
- `ParamSetCollection$clone()`

Method `new()`: Creates a new instance of this `R6` class.

Usage:

`ParamSetCollection$new(sets)`

Arguments:

`sets` (list() of `ParamSet`)

Parameter objects are cloned.

Method `add()`: Adds a set to this collection.

Usage:

`ParamSetCollection$add(p)`

Arguments:

`p` ([ParamSet](#)).

Method `remove_sets()`: Removes sets of given ids from collection.

Usage:

`ParamSetCollection$remove_sets(ids)`

Arguments:

`ids` (`character()`).

Method `subset()`: Only included for consistency. Not allowed to perform on [ParamSetCollections](#).

Usage:

`ParamSetCollection$subset(ids)`

Arguments:

`ids` (`character()`).

Method `clone()`: The objects of this class are cloneable with this method.

Usage:

`ParamSetCollection$clone(deep = FALSE)`

Arguments:

`deep` Whether to make a deep clone.

Description

A [Param](#) to describe untyped parameters.

Super class

`paradox::Param -> ParamUty`

Public fields

`custom_check` (`function()`)

Custom function to check the feasibility.

`repr` (`character(1)`)

Custom field for printing the parameter table.

Active bindings

```

lower (numeric(1))
  Lower bound. Always NA for ParamFct, ParamLgl and ParamUty.

upper (numeric(1))
  Upper bound. Always NA for ParamFct, ParamLgl and ParamUty.

levels (character() | NULL)
  Set of allowed levels. Always NULL for ParamDbl, ParamInt and ParamUty. Always c(TRUE, FALSE) for ParamLgl.

nlevels (integer(1) | Inf)
  Number of categorical levels. Always Inf for ParamDbl and ParamUty. The number of integers in the range [lower, upper], or Inf if unbounded for ParamInt. Always 2 for ParamLgl.

is_bounded (logical(1))
  Are the bounds finite? Always TRUE for ParamFct and ParamLgl. Always FALSE for ParamUty.

storage_type (character(1))
  Data type when values of this parameter are stored in a data table or sampled. Always "numeric" for ParamDbl. Always "character" for ParamFct. Always "integer" for ParamInt. Always "logical" for ParamLgl. Always "list" for ParamUty.

```

Methods

Public methods:

- ParamUty\$new()
- ParamUty\$clone()

Method new(): Creates a new instance of this R6 class.

Usage:

```
ParamUty$new(
  id,
  default = NO_DEF,
  tags = character(),
  custom_check = NULL,
  repr = substitute(default)
)
```

Arguments:

id (character(1))
 Identifier of the object.

default (any)
 Default value. Can be from the domain of the parameter or an element of `special_vals`. Has value `NO_DEF` if no default exists. NULL can be a valid default. The value has no effect on `ParamSet$values` or the behavior of `ParamSet$check()`, `$test()` or `$assert()`. The default is intended to be used for documentation purposes. ‘

tags (character())
 Arbitrary tags to group and subset parameters. Some tags serve a special purpose:

- "required" implies that the parameters has to be given when setting values in [ParamSet](#).

`custom_check (function())`

Custom function to check the feasibility. Function which checks the input. Must return 'TRUE' if the input is valid and a string with the error message otherwise. Defaults to NULL, which means that no check is performed.

`repr (character(1))`

Custom representation string. Used for parameter table in help pages.

Method `clone()`: The objects of this class are cloneable with this method.

Usage:

`ParamUty$clone(deep = FALSE)`

Arguments:

`deep` Whether to make a deep clone.

Other Params: [ParamDbl](#), [ParamFct](#), [ParamInt](#), [ParamLgl](#), [Param](#)

Examples

```
ParamUty$new("untyped", default = Inf)
```

ps

Construct a ParamSet using Short Forms

Description

The `ps()` short form constructor uses [Domain](#) objects (`p_dbl`, `p_fct`, ...) to construct [ParamSets](#) in a succinct and readable way.

For more specifics also see the documentation of [Domain](#).

Usage

```
ps(..., .extra_trafo = NULL, .allow_dangling_dependencies = FALSE)
```

Arguments

...

[\(Domain | Param\)](#)

Named arguments of [Domain](#) or [Param](#) objects. The [ParamSet](#) will be constructed of the given [Params](#), or of [Params](#) constructed from the given domains. The names of the arguments will be used as \$id (the \$id of [Param](#) arguments are ignored).

`.extra_trafo`

[\(function\(x, param_set\)\)](#)

Transformation to set the resulting [ParamSet](#)'s \$trafo value to. This is in addition to any trafo of [Domain](#) objects given in ..., and will be run after transformations of individual parameters were performed.

```
.allow_dangling_dependencies
  (logical)
```

Whether dependencies depending on parameters that are not present should be allowed. A parameter `x` having `depends = y == 0` if `y` is not present in the `ps()` call would usually throw an error, but if dangling dependencies are allowed, the dependency is added regardless. This is usually a bad idea and mainly for internal use. Dependencies between `ParamSets` when using `to_tune()` can be realized using this.

Value

A `ParamSet` object.

See Also

Other `ParamSet` construction helpers: `Domain`, `to_tune()`

Examples

```
pars = ps(
  a = p_int(0, 10),
  b = p_int(upper = 20),
  c = p_dbl(),
  e = p_fct(letters[1:3]),
  f = p_uty(custom_check = checkmate::check_function)
)
print(pars)

pars = ps(
  a = p_dbl(0, 1, trafo = exp),
  b = p_dbl(0, 1, trafo = exp),
  .extra_trafo = function(x, ps) {
    x$c <- x$a + x$b
    x
  }
)

# See how the addition happens after exp()ing:
pars$trafo(list(a = 0, b = 0))

pars$values = list(
  a = to_tune(ps(x = p_int(0, 1),
    .extra_trafo = function(x, param_set) list(a = x$x)
  )),
  # make 'y' depend on 'x', but they are defined in different ParamSets
  # Therefore we need to allow dangling dependencies here.
  b = to_tune(ps(y = p_int(0, 1, depends = x == 1),
    .extra_trafo = function(x, param_set) list(b = x$y),
    .allow_dangling_dependencies = TRUE
  )))
)
```

```
pars$search_space()
```

psc *Create a ParamSet Collection*

Description

Creates a [ParamSetCollection](#).

Usage

```
psc(...)
```

Arguments

...	(any)
	The ParamSets from which to create the collection.

Sampler *Sampler Class*

Description

This is the abstract base class for sampling objects like [Sampler1D](#), [SamplerHierarchical](#) or [SamplerJointIndep](#).

Public fields

param_set (ParamSet)	
	Domain / support of the distribution we want to sample from.

Methods

Public methods:

- [Sampler\\$new\(\)](#)
- [Sampler\\$sample\(\)](#)
- [Sampler\\$format\(\)](#)
- [Sampler\\$print\(\)](#)
- [Sampler\\$clone\(\)](#)

Method new(): Creates a new instance of this [R6](#) class.

Note that this object is typically constructed via derived classes, e.g., [Sampler1D](#).

Usage:

```
Sampler$new(param_set)
```

Arguments:

`param_set` ([ParamSet](#))

Domain / support of the distribution we want to sample from. ParamSet is cloned on construction.

Method `sample()`: Sample n values from the distribution.

Usage:

`Sampler$sample(n)`

Arguments:

`n` ([integer\(1\)](#)).

Returns: [Design](#).

Method `format()`: Helper for print outputs.

Usage:

`Sampler=format(...)`

Arguments:

`...` (ignored).

Method `print()`: Printer.

Usage:

`Sampler/print(...)`

Arguments:

`...` (ignored).

Method `clone()`: The objects of this class are cloneable with this method.

Usage:

`Sampler$clone(deep = FALSE)`

Arguments:

`deep` Whether to make a deep clone.

See Also

[SamplerHierarchical](#), [SamplerJointIndep](#), [SamplerUnif](#)

*Sampler1D**Sampler1D Class*

Description

1D sampler, abstract base class for Sampler like [Sampler1DUnif](#), [Sampler1DRfun](#), [Sampler1DCateg](#) and [Sampler1DNormal](#).

Super class

[paradox::Sampler](#) -> *Sampler1D*

Active bindings

param ([Param](#))

Returns the one Parameter that is sampled from.

Methods

Public methods:

- [Sampler1D\\$new\(\)](#)
- [Sampler1D\\$clone\(\)](#)

Method new(): Creates a new instance of this [R6](#) class.

Note that this object is typically constructed via derived classes, e.g., [Sampler1DUnif](#).

Usage:

`Sampler1D$new(param)`

Arguments:

param ([Param](#))

Domain / support of the distribution we want to sample from.

Method clone(): The objects of this class are cloneable with this method.

Usage:

`Sampler1D$clone(deep = FALSE)`

Arguments:

`deep` Whether to make a deep clone.

See Also

Other Sampler: [Sampler1DCateg](#), [Sampler1DNormal](#), [Sampler1DRfun](#), [Sampler1DUnif](#), [SamplerHierarchical](#), [SamplerJointIndep](#), [SamplerUnif](#), [Sampler](#)

Description

Sampling from a discrete distribution, for a [ParamFct](#) or [ParamLgl](#).

Super classes

[paradox::Sampler](#) -> [paradox::Sampler1D](#) -> Sampler1DCateg

Public fields

prob (numeric() | NULL)
Numeric vector of param\$levels probabilities.

Methods

Public methods:

- [Sampler1DCateg\\$new\(\)](#)
- [Sampler1DCateg\\$clone\(\)](#)

Method new(): Creates a new instance of this [R6](#) class.

Usage:

Sampler1DCateg\$new(param, prob = NULL)

Arguments:

param ([Param](#))

Domain / support of the distribution we want to sample from.

prob (numeric() | NULL)

Numeric vector of param\$levels probabilities, which is uniform by default.

Method clone(): The objects of this class are cloneable with this method.

Usage:

Sampler1DCateg\$clone(deep = FALSE)

Arguments:

deep Whether to make a deep clone.

See Also

Other Sampler: [Sampler1DNormal](#), [Sampler1DRfun](#), [Sampler1DUnif](#), [Sampler1D](#), [SamplerHierarchical](#), [SamplerJointIndep](#), [SamplerUnif](#), [Sampler](#)

`Sampler1DNormal` *Sampler1DNormal Class*

Description

Normal sampling (potentially truncated) for `ParamDbl`.

Super classes

`paradox::Sampler` -> `paradox::Sampler1D` -> `paradox::Sampler1DRfun` -> `Sampler1DNormal`

Active bindings

<code>mean (numeric(1))</code>	Mean parameter of the normal distribution.
<code>sd (numeric(1))</code>	SD parameter of the normal distribution.

Methods

Public methods:

- `Sampler1DNormal$new()`
- `Sampler1DNormal$clone()`

Method `new()`: Creates a new instance of this `R6` class.

Usage:

`Sampler1DNormal$new(param, mean = NULL, sd = NULL)`

Arguments:

`param (Param)`

Domain / support of the distribution we want to sample from.

`mean (numeric(1))`

Mean parameter of the normal distribution. Default is `mean(c(param$lower, param$upper))`.

`sd (numeric(1))`

SD parameter of the normal distribution. Default is `(param$upper - param$lower)/4`.

Method `clone()`: The objects of this class are cloneable with this method.

Usage:

`Sampler1DNormal$clone(deep = FALSE)`

Arguments:

`deep` Whether to make a deep clone.

See Also

Other Sampler: `Sampler1DCateg`, `Sampler1DRfun`, `Sampler1DUnif`, `Sampler1D`, `SamplerHierarchical`, `SamplerJointIndep`, `SamplerUnif`, `Sampler`

Sampler1DRfun

Sampler1DRfun Class

Description

Arbitrary sampling from 1D RNG functions from R.

Super classes

`paradox::Sampler -> paradox::Sampler1D -> Sampler1DRfun`

Public fields

`rfun (function())`

Random number generator function.

`trunc (logical(1))`

TRUE enables naive rejection sampling, so we stay inside of [lower, upper].

Methods

Public methods:

- `Sampler1DRfun$new()`
- `Sampler1DRfun$clone()`

Method `new()`: Creates a new instance of this [R6](#) class.

Usage:

`Sampler1DRfun$new(param, rfun, trunc = TRUE)`

Arguments:

`param (Param)`

Domain / support of the distribution we want to sample from.

`rfun (function())`

Random number generator function, e.g. `rexp` to sample from exponential distribution.

`trunc (logical(1))`

TRUE enables naive rejection sampling, so we stay inside of [lower, upper].

Method `clone()`: The objects of this class are cloneable with this method.

Usage:

`Sampler1DRfun$clone(deep = FALSE)`

Arguments:

`deep` Whether to make a deep clone.

Sampler1DUnif*Sampler1DUnif Class*

Description

Uniform random sampler for arbitrary (bounded) parameters.

Super classes

`paradox::Sampler -> paradox::Sampler1D -> Sampler1DUnif`

Methods

Public methods:

- `Sampler1DUnif$new()`
- `Sampler1DUnif$clone()`

Method `new():` Creates a new instance of this [R6](#) class.

Usage:

`Sampler1DUnif$new(param)`

Arguments:

`param` ([Param](#))

Domain / support of the distribution we want to sample from.

Method `clone():` The objects of this class are cloneable with this method.

Usage:

`Sampler1DUnif$clone(deep = FALSE)`

Arguments:

`deep` Whether to make a deep clone.

See Also

Other Sampler: [Sampler1DCateg](#), [Sampler1DNormal](#), [Sampler1DRfun](#), [Sampler1D](#), [SamplerHierarchical](#), [SamplerJointIndep](#), [SamplerUnif](#), [Sampler](#)

SamplerJointIndep *SamplerJointIndep Class*

Description

Create joint, independent sampler out of multiple other samplers.

Super class

[paradox::Sampler](#) -> SamplerJointIndep

Public fields

`samplers (list())`
List of [Sampler](#) objects.

Methods

Public methods:

- [SamplerJointIndep\\$new\(\)](#)
- [SamplerJointIndep\\$clone\(\)](#)

Method `new()`: Creates a new instance of this [R6](#) class.

Usage:

`SamplerJointIndep$new(samplers)`

Arguments:

`samplers (list())`
List of [Sampler](#) objects.

Method `clone()`: The objects of this class are cloneable with this method.

Usage:

`SamplerJointIndep$clone(deep = FALSE)`

Arguments:

`deep` Whether to make a deep clone.

See Also

Other Sampler: [Sampler1DCateg](#), [Sampler1DNormal](#), [Sampler1DRfun](#), [Sampler1DUnif](#), [Sampler1D](#),
[SamplerHierarchical](#), [SamplerUnif](#), [Sampler](#)

Description

Uniform random sampling for an arbitrary (bounded) [ParamSet](#). Constructs 1 uniform sampler per [Param](#), then passes them to [SamplerHierarchical](#). Hence, also works for [ParamSets](#) sets with dependencies.

Super classes

[paradox::Sampler](#) -> [paradox::SamplerHierarchical](#) -> SamplerUnif

Methods

Public methods:

- [SamplerUnif\\$new\(\)](#)
- [SamplerUnif\\$clone\(\)](#)

Method [new\(\)](#): Creates a new instance of this [R6](#) class.

Usage:

`SamplerUnif$new(param_set)`

Arguments:

`param_set` ([ParamSet](#))

Domain / support of the distribution we want to sample from. ParamSet is cloned on construction.

Method [clone\(\)](#): The objects of this class are cloneable with this method.

Usage:

`SamplerUnif$clone(deep = FALSE)`

Arguments:

`deep` Whether to make a deep clone.

The TuneToken object's internals are subject to change and should not be relied upon. TuneToken objects should only be constructed via `to_tune()`, and should only be used by giving them to `$values` of a [ParamSet](#).

Usage

```
to_tune(...)
```

Arguments

... if given, restricts the range to be tuning over, as described above.

Value

A TuneToken object.

See Also

Other ParamSet construction helpers: [Domain](#), [ps\(\)](#)

Examples

```
params = ParamSet$new(list(
  ParamInt$new("int", 0, 10),
  ParamInt$new("int_unbounded"),
  ParamDbl$new("dbl", 0, 10),
  ParamDbl$new("dbl_unbounded"),
  ParamDbl$new("dbl_bounded_below", lower = 1),
  ParamFct$new("fct", c("a", "b", "c")),
  ParamUty$new("uty1"),
  ParamUty$new("uty2"),
  ParamUty$new("uty3"),
  ParamUty$new("uty4"),
  ParamUty$new("uty5")
))

params$values = list(
  # tune over entire range of `int`, 0..10:
  int = to_tune(),

  # tune over 2..7:
  int_unbounded = to_tune(2, 7),

  # tune on a log scale in range 1..10;
  # recognize upper bound of 10 automatically, but restrict lower bound to 1:
  dbl = to_tune(lower = 1, logscale = TRUE),
  ## This is equivalent to the following:
  # dbl = to_tune(p_dbl(log(1), log(10), trafo = exp)),

  # nothing keeps us from tuning a dbl over integer values
  dbl_unbounded = to_tune(p_int(1, 10)),
```

```

# tune over values "a" and "b" only
fct = to_tune(c("a", "b")),

# tune over integers 2..8.
# ParamUty needs type information in form of p_xxx() in to_tune.
uty1 = to_tune(p_int(2, 8)),

# tune uty2 like a factor, trying 1, 10, and 100:
uty2 = to_tune(c(1, 10, 100)),

# tune uty3 like a factor. The factor levels are the names of the list
# ("exp", "square"), but the trafo will generate the values from the list.
# This way you can tune an objective that has function-valued inputs.
uty3 = to_tune(list(exp = exp, square = function(x) x^2)),

# tune through multiple parameters. When doing this, the ParamSet in tune()
# must have the trafo that generates a list with one element and the right
# name:
uty4 = to_tune(ps(
  base = p_dbl(0, 1),
  exp = p_int(0, 3),
  .extra_trafo = function(x, param_set) {
    list(uty4 = x$base ^ x$exp)
  }
)),

# not all values need to be tuned!
uty5 = 100
)

print(params$values)

print(params$search_space())

# Change `values` directly and generate new `search_space()` to play around
params$values$uty3 = 8
params$values$uty2 = to_tune(c(2, 4, 8))

print(params$search_space())

# Notice how `logscale` applies `log()` to lower and upper bound pre-trafo:
params = ParamSet$new(list(ParamDbl$new("x")))

params$values$x = to_tune(1, 100, logscale = TRUE)

print(params$search_space())

grid = generate_design_grid(params$search_space(), 3)

# The grid is equidistant within log-bounds pre-trafo:
print(grid)

```

```
# But the values are on a log scale scale with desired bounds after trafo:  
print(grid$transpose())
```
