

# Package ‘SEMID’

January 30, 2026

**Type** Package

**Title** Identifiability of Linear Structural Equation Models

**Version** 0.5.0

**Date** 2026-01-30

**Maintainer** Nils Sturma <nils.sturma@epfl.ch>

**Description** Provides routines to check identifiability of linear structural equation models and factor analysis models. The routines are based on the graphical representation of structural equation models.

**License** GPL (>= 2)

**Encoding** UTF-8

**URL** <https://github.com/Lucaweihs/SEMID>

**BugReports** <https://github.com/Lucaweihs/SEMID/issues>

**Imports** R.oo (>= 1.20.0), R.methodsS3, igraph (>= 1.0.1), R.utils (>= 2.3.0), rje

**Suggests** testthat

**NeedsCompilation** no

**Repository** CRAN

**RoxygenNote** 7.3.3

**Author** Rina Foygel Barber [aut],  
Mathias Drton [aut],  
Miriam Kranzlmüller [aut],  
Nils Sturma [cre, aut],  
Luca Weihs [aut]

**Date/Publication** 2026-01-30 08:10:02 UTC

## Description

SEMID provides a number of methods for testing the global/generic identifiability of mixed graphs and latent-factor graphs.

## Details

The only functions you're likely to need from **SEMID** are `semID` and `lfhtcID`. A complete description of all package features, along with examples, can be found at <https://github.com/LucaWeihs/SEMID>.

## Examples

```
###
# Checking the generic identifiability of parameters in a mixed graph.
###

# Mixed graphs are specified by their directed adjacency matrix L and
# bidirected adjacency matrix O.
L = t(matrix(
  c(0, 1, 1, 0, 0,
    0, 0, 1, 1, 1,
    0, 0, 0, 1, 0,
    0, 0, 0, 0, 1,
    0, 0, 0, 0, 0), 5, 5))

O = t(matrix(
  c(0, 0, 0, 1, 0,
    0, 0, 1, 0, 1,
    0, 0, 0, 0, 0,
    0, 0, 0, 0, 0,
    0, 0, 0, 0, 0), 5, 5)); O=O+t(O)

# Create a mixed graph object
graph = MixedGraph(L, O)

# We can plot what this mixed graph looks like, blue edges are directed
# red edges are bidirected.
plot(graph)

# Without using decomposition techniques we can't identify all nodes
# just using the half-trek criterion
htcID(graph, tianDecompose = FALSE)

# The edgewiseTSID function can show that all edges are generically
# identifiable without preprocessing with decomposition techniques
edgewiseTSID(graph, tianDecompose = FALSE)
```

```

# The above shows that all edges in the graph are generically identifiable.
# See the help of edgewiseTSID to find out more information about what
# else is returned by edgewiseTSID.

###
# Checking generic parameter identifiability using the generalGenericID
# function
###

L = t(matrix(
  c(0, 1, 0, 0, 0,
    0, 0, 0, 1, 1,
    0, 0, 0, 1, 0,
    0, 1, 0, 0, 1,
    0, 0, 0, 1, 0), 5, 5))

O = t(matrix(
  c(0, 0, 0, 0, 0,
    0, 0, 1, 0, 1,
    0, 0, 0, 1, 0,
    0, 0, 0, 0, 0,
    0, 0, 0, 0, 0), 5, 5)); O=O+t(O)

# Create a mixed graph object
graph = MixedGraph(L, O)

# Now lets define an "identification step" function corresponding to
# using the edgewise identification algorithm but with subsets
# controlled by 1.
restrictedEdgewiseIdentifyStep <- function(mixedGraph,
                                           unsolvedParents,
                                           solvedParents,
                                           identifier) {
  return(edgewiseIdentifyStep(mixedGraph, unsolvedParents,
                              solvedParents, identifier,
                              subsetSizeControl = 1))
}

# Now we run an identification algorithm that iterates between the
# htc and the "restricted" edgewise identification algorithm
generalGenericID(graph, list(htcIdentifyStep,
                             restrictedEdgewiseIdentifyStep),
                 tianDecompose = FALSE)

# We can do better (fewer unsolved parents) if we don't restrict the edgewise
# identifier algorithm as much
generalGenericID(graph, list(htcIdentifyStep, edgewiseIdentifyStep),
                 tianDecompose = FALSE)

###
# Checking the generic identifiability of parameters in a latent-factor graph.
###

```

```

# Latent digraphs are specified by their directed adjacency matrix L
library(SEMID)
L = matrix(c(0, 1, 0, 0, 0, 0,
            0, 0, 1, 0, 0, 0,
            0, 0, 0, 0, 0, 0,
            0, 0, 0, 0, 1, 0,
            0, 0, 0, 0, 0, 0,
            1, 1, 1, 1, 1, 0), 6, 6, byrow=TRUE)
observedNodes = seq(1,5)
latentNodes = c(6)

# Create the latent digraph object corresponding to L
g = LatentDigraph(L, observedNodes, latentNodes)

# Plot latent digraph
plot(g)

# We can identify all nodes by the latent-factor half-trek criterion
lfhtcID(g)

```

---

ancestors

*All ancestors of a collection of nodes*

---

### Description

Finds all the ancestors of a collection of nodes. These ancestors DO include the nodes themselves (every node is considered an ancestor of itself).

### Usage

```
ancestors(this, nodes, ...)
```

```
## S3 method for class 'LatentDigraphFixedOrder'
ancestors(this, nodes, includeObserved = T, includeLatents = T, ...)
```

```
## S3 method for class 'LatentDigraph'
ancestors(this, nodes, includeObserved = T, includeLatents = T, ...)
```

```
## S3 method for class 'MixedGraph'
ancestors(this, nodes, ...)
```

### Arguments

<code>this</code>	the graph object
<code>nodes</code>	the nodes from which to find all ancestors
<code>...</code>	ignored.

includeObserved if TRUE includes observed nodes in the returned set.  
 includeLatents if TRUE includes latent nodes in the returned set.

**Value**

the ancestors of the nodes in the observed part of the graph.

---

ancestralID *Determines which edges in a mixed graph are ancestralID-identifiable*

---

**Description**

Uses the an identification criterion of Drton and Weihs (2015); this version of the algorithm is somewhat different from Drton and Weihs (2015) in that it also works on cyclic graphs. The original version of the algorithm can be found in the function [graphID.ancestralID](#).

**Usage**

```
ancestralID(mixedGraph, tianDecompose = T)
```

**Arguments**

mixedGraph a [MixedGraph](#) object representing the L-SEM.  
 tianDecompose TRUE or FALSE determining whether or not the Tian decomposition should be used before running the current generic identification algorithm. In general letting this be TRUE will make the algorithm faster and more powerful.

**Value**

see the return of [generalGenericID](#).

---

ancestralIdentifyStep *Perform one iteration of ancestral identification.*

---

**Description**

A function that does one step through all the nodes in a mixed graph and tries to determine if directed edge coefficients are generically identifiable by leveraging decomposition by ancestral subsets. See Algorithm 1 of Drton and Weihs (2015); this version of the algorithm is somewhat different from Drton and Weihs (2015) in that it also works on cyclic graphs.

**Usage**

```
ancestralIdentifyStep(mixedGraph, unsolvedParents, solvedParents, identifier)
```

**Arguments**

- mixedGraph** a `MixedGraph` object representing the mixed graph.
- unsolvedParents** a list whose *i*th index is a vector of all the parents *j* of *i* in *G* which for which the edge *j*->*i* is not yet known to be generically identifiable.
- solvedParents** the complement of `unsolvedParents`, a list whose *i*th index is a vector of all parents *j* of *i* for which the edge *i*->*j* is known to be generically identifiable (perhaps by other algorithms).
- identifier** an identification function that must produce the identifications corresponding to those in solved parents. That is `identifier` should be a function taking a single argument `Sigma` (any generically generated covariance matrix corresponding to the mixed graph) and returns a list with two named arguments
- Lambda** denote the number of nodes in `mixedGraph` as *n*. Then `Lambda` is an *n*x*n* matrix whose *i,j*th entry
1. equals 0 if *i* is not a parent of *j*,
  2. equals NA if *i* is a parent of *j* but `identifier` cannot identify it generically,
  3. equals the (generically) unique value corresponding to the weight along the edge *i*->*j* that was used to produce `Sigma`.
- Omega** just as `Lambda` but for the bidirected edges in the mixed graph such that if *j* is in `solvedParents[[i]]` we must have that `Lambda[j,i]` is not NA.

**Value**

a list with four components:

`identifiedEdges` a matrix *r*x2 matrix where *r* is the number of edges that were identified by this function call and `identifiedEdges[i,1]` -> `identifiedEdges[i,2]` was the *i*th edge identified

`unsolvedParents` as the input argument but updated with any newly identified edges

`solvedParents` as the input argument but updated with any newly identified edges

`identifier` as the input argument but updated with any newly identified edges

---

bidirectedComponents *Get bidirected components of a mixed graph*

---

**Description**

Returns induced subgraphs of connected bidirected components with more than 1 node.

**Usage**

```
bidirectedComponents(graph)
```

**Arguments**

graph            a [MixedGraph](#) object representing the mixed graph.

**Value**

list, where each object is a [MixedGraph](#) with at least two nodes.

---

checkLocalBBCriterion *Check Local BB-Criterion*

---

**Description**

checks whether a graph is recursively identifiable by only using the local BB-criterion

**Usage**

```
checkLocalBBCriterion(adjMatrix, latentNodes, observedNodes)
```

**Arguments**

adjMatrix        of the graph  
 latentNodes     set of latent nodes  
 observedNodes   set of observed nodes

**Value**

a list consisting of a Boolean, whether the graph is sign-identifiable and if yes, a list consisting of the sets

**References**

Sturma, N., Kranzlmüller, M., Portakal, I., and Drton, M. (2025) Matching Criterion for Identifiability in Sparse Factor Analysis. [arXiv:2502.02986](#)

---

 checkMatchingCriterion

*Check Matching Criterion*

---

### Description

for a latent node  $h$ , find a single observed node  $v$  and two sets of observed nodes  $W$  and  $U$  so that the tuple satisfies the matching criterion

### Usage

```
checkMatchingCriterion(
  flowGraphAdjMatrix,
  adjMatrix,
  h,
  latentNodes,
  observedNodes,
  maxCard = length(observedNodes)
)
```

### Arguments

flowGraphAdjMatrix	matrix representing the basis flow graph for any latent node $h$
adjMatrix	of the graph
$h$	latent node for which a tuple satisfying the criterion is sought
latentNodes	set of latent nodes
observedNodes	set of observed nodes
maxCard	maximum size of set $W$

### Value

a list consisting of a Boolean, whether the graph is sign-identifiable and if yes, a list consisting of the sets

### References

Sturma, N., Kranzlmüller, M., Portakal, I., and Drton, M. (2025) Matching Criterion for Identifiability in Sparse Factor Analysis. arXiv:2502.02986

---

children	<i>All children of a collection of nodes.</i>
----------	---

---

**Description**

Returns all children of the collection (does not necessarily include the input nodes themselves unless they are parents of one another).

**Usage**

```
children(this, nodes, ...)

## S3 method for class 'LatentDigraphFixedOrder'
children(this, nodes, includeObserved = T, includeLatents = T, ...)

## S3 method for class 'LatentDigraph'
children(this, nodes, includeObserved = T, includeLatents = T, ...)

## S3 method for class 'MixedGraph'
children(this, nodes, ...)
```

**Arguments**

this	the graph object.
nodes	nodes the nodes of which to find the children
...	ignored.
includeObserved	if TRUE includes observed nodes in the returned set.
includeLatents	if TRUE includes latent nodes in the returned set.

**Value**

the observed children

---

createAncestralIdentifier	<i>Create an ancestral identification function.</i>
---------------------------	---

---

**Description**

A helper function for [ancestralIdentifyStep](#), creates an identifier function based on its given parameters. This created identifier function will identify the directed edges from 'targets' to 'node.'

**Usage**

```
createAncestralIdentifier(
  idFunc,
  sources,
  targets,
  node,
  htrSources,
  ancestralSubset,
  cComponent
)
```

**Arguments**

idFunc	identification of edge coefficients often requires that other edge coefficients already be identified. This argument should be a function that produces all such identifications. The newly created identifier function will return these identifications along with its own.
sources	the sources of the half-trek system.
targets	the targets of the half-trek system (these should be the parents of node).
node	the node for which all incoming edges are to be identified (the tails of which are targets).
htrSources	the nodes in sources which are half-trek reachable from node. All incoming edges to these sources should be identified by idFunc for the newly created identification function to work.
ancestralSubset	an ancestral subset of the graph containing node.
cComponent	a list corresponding to the connected component containing node in the sub-graph induced by ancestralSubset. See <a href="#">tianDecompose</a> for how such connected component lists are formed.

**Value**

an identification function

---

```
createEdgewiseIdentifier
```

*Create an edgewise identification function*

---

**Description**

A helper function for [edgewiseIdentifyStep](#), creates an identifier function based on its given parameters. This created identifier function will identify the directed edges from 'targets' to 'node.'

**Usage**

```

createEdgewiseIdentifier(
  idFunc,
  sources,
  targets,
  node,
  solvedNodeParents,
  sourceParentsToRemove
)

```

**Arguments**

idFunc	identification of edge coefficients often requires that other edge coefficients already be identified. This argument should be a function that produces all such identifications. The newly created identifier function will return these identifications along with its own.
sources	the sources of the half-trek system.
targets	the targets of the half-trek system (these should be the parents of node).
node	the node for which all incoming edges are to be identified (the tails of which are targets).
solvedNodeParents	the parents of node that have been solved
sourceParentsToRemove	a list of the parents of the sources that should have their edge to their respect source removed.

**Value**

an identification function

---

createHtcIdentifier    *Create an htc identification function.*

---

**Description**

A helper function for [htcIdentifyStep](#), creates an identifier function based on its given parameters. This created identifier function will identify the directed edges from 'targets' to 'node.'

**Usage**

```
createHtcIdentifier(idFunc, sources, targets, node, htrSources)
```

**Arguments**

idFunc	identification of edge coefficients often requires that other edge coefficients already be identified. This argument should be a function that produces all such identifications. The newly created identifier function will return these identifications along with its own.
sources	the sources of the half-trek system.
targets	the targets of the half-trek system (these should be the parents of node).
node	the node for which all incoming edges are to be identified (the tails of which are targets).
htrSources	the nodes in sources which are half-trek reachable from node. All incoming edges to these sources should be identified by idFunc for the newly created identification function to work.

**Value**

an identification function

---

createIdentifierBaseCase

*Create an identifier base case*

---

**Description**

Identifiers are functions that take as input a covariance matrix Sigma corresponding to some mixed graph G and, from that covariance matrix, identify some subset of the coefficients in the mixed graph G. This function takes as input the matrices, L and O, defining G and creates an identifier that does not identify any of the coefficients of G. This is useful as a base case when building more complex identification functions.

**Usage**

```
createIdentifierBaseCase(L, O)
```

**Arguments**

L	Adjacency matrix for the directed part of the path diagram/mixed graph; an edge pointing from i to j is encoded as $L[i,j]=1$ and the lack of an edge between i and j is encoded as $L[i,j]=0$ . There should be no directed self loops, i.e. no i such that $L[i,i]=1$ .
O	Adjacency matrix for the bidirected part of the path diagram/mixed graph. Edges are encoded as for the L parameter. Again there should be no self loops. Also this matrix will be coerced to be symmetric so it is only necessary to specify an edge once, i.e. if $O[i,j]=1$ you may, but are not required to, also have $O[j,i]=1$ .

**Value**

a function that takes as input a covariance matrix compatible with the mixed graph defined by L/O and returns a list with two named components:

Lambda a matrix equal to L but with NA values instead of 1s

Omega a matrix equal to O but with NA values instead of 1s

When building more complex identifiers these NAs will be replaced by the value that can be identified from Sigma.

---

`createLFHtcIdentifier` *Create a latent-factor half-trek criterion identification function.*

---

**Description**

A helper function for `lfhtcIdentifyStep`, creates an identifier function based on its given parameters. This created identifier function will identify the directed edges from 'targets' to 'node.'

**Usage**

```
createLFHtcIdentifier(idFunc, v, Y, Z, parents, reachableY)
```

**Arguments**

<code>idFunc</code>	identification of edge coefficients often requires that other edge coefficients already be identified. This argument should be a function that produces all such identifications. The newly created identifier function will return these identifications along with its own.
<code>v</code>	the node for which all incoming edges are to be identified (the tails of which are targets).
<code>Y</code>	the sources of the latent-factor half-trek system.
<code>Z</code>	the nodes that are reached from Y via an latent-factor half-trek of the form $y \leftarrow h \rightarrow z$ where h is an element of L.
<code>parents</code>	the parents of node v.
<code>reachableY</code>	the nodes in Y which are latent-factor half-trek reachable from Z or v by avoiding the nodes in L. All incoming edges to these nodes should be identified by idFunc the newly created identification function to work.

**Value**

an identification function

**References**

Barber, R. F., Drton, M., Sturma, N., and Weihs L. (2022). Half-Trek Criterion for Identifiability of Latent Variable Models. *arXiv preprint* arXiv:2201.04457

---

```
createLFIdentifierBaseCase
```

*Create an latent identifier base case*

---

### Description

Identifiers are functions that take as input a covariance matrix  $\Sigma$  corresponding to some latent digraph  $G$  and, from that covariance matrix, identify some subset of the coefficients corresponding to the direct causal effects in the latent digraph  $G$ . This function takes as input the digraph  $G$  and creates an identifier that does not identify any of the direct causal effects. This is useful as a base case when building more complex identification functions.

### Usage

```
createLFIdentifierBaseCase(graph)
```

### Arguments

`graph` a [LatentDigraph](#) object representing the latent-factor graph. All latent nodes in this graph should be source nodes (i.e. have no parents).

### Value

a function that takes as input a covariance matrix compatible with the latent digraph defined by  $L$  and returns a list with two named components:

`Lambda` a matrix equal to the observed part of `graph$L()` but with NA values instead of 1s

`Omega` a matrix equal to `graph$O()` but with NA values for coefficients not equal to zero.

When building more complex identifiers these NAs will be replaced by the value that can be identified from the covariance matrix corresponding to  $G$ .

---

```
createSimpleBiDirIdentifier
```

*Identify bidirected edges if all directed edges are identified*

---

### Description

Creates an identifier function that assumes that all directed edges have already been identified and then is able to identify all bidirected edges simultaneously.

### Usage

```
createSimpleBiDirIdentifier(idFunc)
```

**Arguments**

idFunc            an identifier function that identifies all directed edges

**Value**

a new identifier function that identifies everything.

---

createTrekFlowGraph    *Helper function to create a flow graph.*

---

**Description**

Helper function to create a flow graph.

**Usage**

```
createTrekFlowGraph(this, ...)

## S3 method for class 'LatentDigraphFixedOrder'
createTrekFlowGraph(this, ...)
```

**Arguments**

this            the graph object  
...            ignored

---

createTrekSeparationIdentifier  
*Create an trek separation identification function*

---

**Description**

A helper function for [trekSeparationIdentifyStep](#), creates an identifier function based on its given parameters. This created identifier function will identify the directed edge from 'parent' to 'node.'

**Usage**

```
createTrekSeparationIdentifier(
  idFunc,
  sources,
  targets,
  node,
  parent,
  solvedParents
)
```

**Arguments**

idFunc	identification of edge coefficients often requires that other edge coefficients already be identified. This argument should be a function that produces all such identifications. The newly created identifier function will return these identifications along with its own.
sources	the sources of the half-trek system.
targets	the targets of the half-trek system (these should be the parents of node).
node	the node for which all incoming edges are to be identified (the tails of which are targets).
parent	the parent of node for which the edge node -> parent should be generically identified.
solvedParents	the parents of node that have been solved

**Value**

an identification function

---

createTrGraph	<i>Helper function to create a graph encoding trek reachable relationships.</i>
---------------	---

---

**Description**

Helper function to create a graph encoding trek reachable relationships.

**Usage**

```
createTrGraph(this, ...)

## S3 method for class 'LatentDigraphFixedOrder'
createTrGraph(this, ...)
```

**Arguments**

this	the graph object
...	ignored

---

descendants	<i>Get descendants of a collection of observed nodes</i>
-------------	--

---

**Description**

Finds all descendants of a collection of nodes, this DOES include the nodes themselves (every node is considered a descendant of itself).

**Usage**

```

descendants(this, nodes, ...)

## S3 method for class 'LatentDigraphFixedOrder'
descendants(this, nodes, includeObserved = T, includeLatents = T, ...)

## S3 method for class 'LatentDigraph'
descendants(this, nodes, includeObserved = T, includeLatents = T, ...)

## S3 method for class 'MixedGraph'
descendants(this, nodes, ...)

```

**Arguments**

<code>this</code>	the graph object
<code>nodes</code>	the nodes from which to get the descendants.
<code>...</code>	ignored.
<code>includeObserved</code>	if TRUE includes observed nodes in the returned set.
<code>includeLatents</code>	if TRUE includes latent nodes in the returned set.

---

edgewiseID	<i>Determines which edges in a mixed graph are edgewiseID-identifiable</i>
------------	--

---

**Description**

Uses the edgewise identification criterion of Weihs, Robeva, Robinson, et al. (2017) to determine which edges in a mixed graph are generically identifiable.

**Usage**

```
edgewiseID(mixedGraph, tianDecompose = T, subsetSizeControl = 3)
```

**Arguments**

mixedGraph	a <a href="#">MixedGraph</a> object representing the L-SEM.
tianDecompose	TRUE or FALSE determining whether or not the Tian decomposition should be used before running the current generic identification algorithm. In general letting this be TRUE will make the algorithm faster and more powerful.
subsetSizeControl	a positive integer (Inf allowed) which controls the size of edgesets searched in the edgewiseID algorithm. Suppose, for example, this has value 3. Then if a node $i$ has $n$ parents, this will restrict the algorithm to only look at subsets of the parents of size 1,2,3 and $n-2$ , $n-1$ , $n$ . Making this parameter smaller means the algorithm will be faster but less exhaustive (and hence less powerful).

**Value**

see the return of [generalGenericID](#).

---

edgewiseIdentifyStep *Perform one iteration of edgewise identification.*

---

**Description**

A function that does one step through all the nodes in a mixed graph and tries to identify new edge coefficients using the existence of half-trek systems as described in Weihs, Robeva, Robinson, et al. (2017).

**Usage**

```
edgewiseIdentifyStep(
  mixedGraph,
  unsolvedParents,
  solvedParents,
  identifier,
  subsetSizeControl = Inf
)
```

**Arguments**

mixedGraph	a <a href="#">MixedGraph</a> object representing the mixed graph.
unsolvedParents	a list whose $i$ th index is a vector of all the parents $j$ of $i$ in $G$ which for which the edge $j \rightarrow i$ is not yet known to be generically identifiable.
solvedParents	the complement of <code>unsolvedParents</code> , a list whose $i$ th index is a vector of all parents $j$ of $i$ for which the edge $i \rightarrow j$ is known to be generically identifiable (perhaps by other algorithms).

`identifier` an identification function that must produce the identifications corresponding to those in solved parents. That is `identifier` should be a function taking a single argument `Sigma` (any generically generated covariance matrix corresponding to the mixed graph) and returns a list with two named arguments

**Lambda** denote the number of nodes in `mixedGraph` as  $n$ . Then `Lambda` is an  $n \times n$  matrix whose  $i,j$ th entry

1. equals 0 if  $i$  is not a parent of  $j$ ,
2. equals NA if  $i$  is a parent of  $j$  but `identifier` cannot identify it generically,
3. equals the (generically) unique value corresponding to the weight along the edge  $i \rightarrow j$  that was used to produce `Sigma`.

**Omega** just as `Lambda` but for the bidirected edges in the mixed graph such that if  $j$  is in `solvedParents[[i]]` we must have that `Lambda[j,i]` is not NA.

`subsetSizeControl` a positive integer (Inf allowed) which controls the size of edgesets searched in the `edgewiseID` algorithm. Suppose, for example, this has value 3. Then if a node  $i$  has  $n$  parents, this will restrict the algorithm to only look at subsets of the parents of size 1,2,3 and  $n-2, n-1, n$ . Making this parameter smaller means the algorithm will be faster but less exhaustive (and hence less powerful).

**Value**

see the return of [htcIdentifyStep](#).

---

<code>edgewiseTSID</code>	<i>Determines which edges in a mixed graph are edgewiseID+TS identifiable</i>
---------------------------	---

---

**Description**

Uses the edgewise+TS identification criterion of Weihs, Robeva, Robinson, et al. (2017) to determine which edges in a mixed graph are generically identifiable. In particular this algorithm iterates between the half-trek, edgewise, and trek-separation identification algorithms in an attempt to identify as many edges as possible, this may be very slow.

**Usage**

```
edgewiseTSID(
  mixedGraph,
  tianDecompose = T,
  subsetSizeControl = 3,
  maxSubsetSize = 3
)
```

**Arguments**

mixedGraph	a <a href="#">MixedGraph</a> object representing the L-SEM.
tianDecompose	TRUE or FALSE determining whether or not the Tian decomposition should be used before running the current generic identification algorithm. In general letting this be TRUE will make the algorithm faster and more powerful.
subsetSizeControl	a positive integer (Inf allowed) which controls the size of edgesets searched in the edgewiseID algorithm. Suppose, for example, this has value 3. Then if a node $i$ has $n$ parents, this will restrict the algorithm to only look at subsets of the parents of size 1,2,3 and $n-2, n-1, n$ . Making this parameter smaller means the algorithm will be faster but less exhaustive (and hence less powerful).
maxSubsetSize	a positive integer which controls the maximum subset size considered in the trek-separation identification algorithm. Making this parameter smaller means the algorithm will be faster but less exhaustive (and hence less powerful).

**Value**

see the return of [generalGenericID](#).

---

extmID	<i>Check Extended M-Identifiability</i>
--------	---

---

**Description**

Check Extended M-Identifiability

**Usage**

```
extmID(lambda, maxCard = length(observedNodes))
```

**Arguments**

lambda	adjacency matrix with number of cols = number of latent nodes, number of rows = number of observed nodes
maxCard	(optional) maximum size of set $W$

**Value**

a list consisting of a Boolean, whether the graph is sign-identifiable and if yes, a list consisting of the sets

**References**

Sturma, N., Kranzlmüller, M., Portakal, I., and Drton, M. (2025) Matching Criterion for Identifiability in Sparse Factor Analysis. arXiv:2502.029861

---

findColumnsWithSumOne *A Helper Function for Check ZUTA*

---

### Description

iterative function that tries to find a column with sum=1, delete the row with the 1 in that column, check smaller matrix

### Usage

```
findColumnsWithSumOne(cleanMatrix)
```

### Arguments

cleanMatrix      a matrix without zero columns and rows

### Value

a Boolean whether it finds a column with sum=1 and the new matrix, without the row in which the entry is, fulfills ZUTA

---

flowBetween                      *Flow from one set of nodes to another.*

---

### Description

Flow from one set of nodes to another.

### Usage

```
flowBetween(this, sources, sinks)
```

```
## S3 method for class 'FlowGraph'
flowBetween(this, sources, sinks)
```

### Arguments

this                      the flow graph object  
sources                    the nodes from which flow should start.  
sinks                      the nodes at which the flow should end.

### Value

a list with two named components, value (the size of the computed flow) and activeSources (a vector representing the subset of sources which have non-zero flow out of them for the found max-flow).

---

FlowGraph	<i>Construct FlowGraph object</i>
-----------	-----------------------------------

---

**Description**

Creates an object representing a flow graph.

**Usage**

```
FlowGraph(L = matrix(0,1,1), vertexCaps = 1, edgeCaps = matrix(1,1,1))
```

**Arguments**

L	the adjacency matrix for the flow graph. The (i,j)th of L should be a 1 if there is an edge from i to j and 0 otherwise.
vertexCaps	the capacity of the vertices in the flow graph, should either be a single number or a vector whose ith entry is the capacity of vertex i.
edgeCaps	the capacities of the edges in the the flow graph, should be a matrix of the same dimensions as L with (i,j)th entry the capacity of the i->j edge.

**Value**

An object representing the FlowGraph.

---

generalGenericID	<i>A general generic identification algorithm template.</i>
------------------	---

---

**Description**

A function that encapsulates the general structure of our algorithms for testing generic identifiability. Allows for various identification algorithms to be used in concert, in particular it will use the identifier functions in the list `idStepFunctions` sequentially until it can find no more identifications. The step functions that are currently available for use in `idStepFunctions` are

1. `htcIdentifyStep`,
2. `ancestralIdentifyStep`,
3. `edgewiseIdentifyStep`,
4. `trekSeparationIdentifyStep`.

**Usage**

```
generalGenericID(mixedGraph, idStepFunctions, tianDecompose = T)
```

**Arguments**

- mixedGraph a [MixedGraph](#) object representing the L-SEM.
- idStepFunctions a list of identification step functions
- tianDecompose TRUE or FALSE determining whether or not the Tian decomposition should be used before running the current generic identification algorithm. In general letting this be TRUE will make the algorithm faster and more powerful.

**Value**

returns an object of `class` 'GenericIDResult,' this object is just a list with 9 components:

solvedParents a list whose *i*th element contains a vector containing the subsets of parents of node *i* for which the edge *j*->*i* could be shown to be generically identifiable.

unsolvedParents as for solvedParents but for the unsolved parents.

solvedSiblings as for solvedParents but for the siblings of node *i* (i.e. the bidirected neighbors of *i*).

unsolvedSiblings as for solvedSiblings but for the unsolved siblings of node *i* (i.e. the bidirected neighbors of *i*).

identifier a function that takes a (generic) covariance matrix corresponding to the graph and identifies the edges parameters from solvedParents and solvedSiblings. See [htcIdentifyStep](#) for a more in-depth discussion of identifier functions.

mixedGraph a mixed graph object of the graph.

idStepFunctions a list of functions used to generically identify parameters. For instance, htcID uses the function [htcIdentifyStep](#) to identify edges.

tianDecompose the argument tianDecompose.

call the call made to this function.

---

getAncestors *Get getAncestors of nodes in a graph.*

---

**Description**

Get the getAncestors of a collection of nodes in a graph *g*, the getAncestors DO include the the nodes themselves.

**Usage**

```
getAncestors(g, nodes)
```

**Arguments**

- g* the graph (as an `igraph`).
- nodes* the nodes in the graph of which to get the getAncestors.

**Value**

a sorted vector of all ancestor nodes.

---

getDescendants	<i>Get descendants of nodes in a graph.</i>
----------------	---

---

**Description**

Gets the descendants of a collection of nodes in a graph (all nodes that can be reached by following directed edges from those nodes). Descendants DO include the nodes themselves.

**Usage**

```
getDescendants(g, nodes)
```

**Arguments**

g	the graph (as an igraph).
nodes	the nodes in the graph of which to get the descendants.

**Value**

a sorted vector of all descendants of nodes.

---

getHalfTrekSystem	<i>Determines if a half-trek system exists in the mixed graph.</i>
-------------------	--

---

**Description**

Determines if a half-trek system exists in the mixed graph.

**Usage**

```
getHalfTrekSystem(this, fromNodes, toNodes, ...)
```

```
## S3 method for class 'MixedGraph'
getHalfTrekSystem(
  this,
  fromNodes,
  toNodes,
  avoidLeftNodes = integer(0),
  avoidRightNodes = integer(0),
  avoidRightEdges = integer(0),
  ...
)
```

```

## S3 method for class 'MixedGraph'
getTrekSystem(
  this,
  fromNodes,
  toNodes,
  avoidLeftNodes = integer(0),
  avoidRightNodes = integer(0),
  avoidLeftEdges = integer(0),
  avoidRightEdges = integer(0),
  ...
)

```

### Arguments

<code>this</code>	the mixed graph object
<code>fromNodes</code>	the nodes from which the half-trek system should start. If <code>length(fromNodes) &gt; length(toNodes)</code> will find if there exists any half-trek system from any subset of <code>fromNodes</code> of size <code>length(toNodes)</code> to <code>toNodes</code> .
<code>toNodes</code>	the nodes where the half-trek system should end.
<code>...</code>	ignored.
<code>avoidLeftNodes</code>	a collection of nodes to avoid on the left
<code>avoidRightNodes</code>	a collection of nodes to avoid on the right
<code>avoidRightEdges</code>	a collection of edges between observed nodes in the graph that should not be used on any right hand side of any trek in the trek system.
<code>avoidLeftEdges</code>	a collection of edges between observed nodes in the graph that should not be used on any right hand side of any trek in the trek system.

### Value

a list with two named components, `systemExists` (TRUE if a system exists, FALSE otherwise) and `activeFrom` (the subset of `fromNodes` from which the maximal half-trek system was started).

---

<code>getMaxFlow</code>	<i>Size of largest HT system <math>Y</math> satisfying the HTC for a node <math>v</math> except perhaps having <math> getParents(v)  &lt;  Y </math>.</i>
-------------------------	---

---

### Description

For an input mixed graph  $H$ , constructs the Gflow graph as described in Foygel et al. (2012) for a subgraph  $G$  of  $H$ . A max flow algorithm is then run on Gflow to determine the largest half-trek system in  $G$  to a particular node's `getParents` given a set of allowed nodes. Here  $G$  should consist of a bidirected part and nodes which are not in the bidirected part but are a parent of some node in the bidirected part.  $G$  should contain the node for which to compute the max flow.

**Usage**

```
getMaxFlow(L, 0, allowedNodes, biNodes, inNodes, node)
```

**Arguments**

L	Adjacency matrix for the directed part of the path diagram/mixed graph; an edge pointing from $i$ to $j$ is encoded as $L[i,j]=1$ and the lack of an edge between $i$ and $j$ is encoded as $L[i,j]=0$ . There should be no directed self loops, i.e. no $i$ such that $L[i,i]=1$ .
0	Adjacency matrix for the bidirected part of the path diagram/mixed graph. Edges are encoded as for the L parameter. Again there should be no self loops. Also this matrix will be coerced to be symmetric so it is only necessary to specify an edge once, i.e. if $O[i,j]=1$ you may, but are not required to, also have $O[j,i]=1$ .
allowedNodes	the set of allowed nodes.
biNodes	the set of nodes in the subgraph $G$ which are part of the bidirected part.
inNodes	the nodes of the subgraph $G$ which are not in the bidirected part but are a parent of some node in the bidirected component.
node	the node (as an integer) for which the maxflow the largest half trek system

**Value**

See title.

**References**

Foygel, R., Draisma, J., and Drton, M. (2012) Half-trek criterion for generic identifiability of linear structural equation models. *Ann. Statist.* 40(3): 1682-1713.

---

getMixedCompForNode     *Get the mixed component of a node in a mixed subgraph.*

---

**Description**

For an input mixed graph  $H$  and set of nodes  $A$ , let  $G_A$  be the subgraph of  $H$  on the nodes  $A$ . This function returns the mixed component of  $G_A$  containing a specified node.

**Usage**

```
getMixedCompForNode(dG, bG, subNodes, node)
```

**Arguments**

dG	a directed graph representing the directed part of the mixed graph.
bG	an undirected graph representing the undirected part of the mixed graph.
subNodes	an ancestral set of nodes in the mixed graph, this set should include the node for which the mixed component could be found.
node	the node for which the mixed component is found.

**Value**

a list with two named elements: biNodes - the nodes of the mixed graph in the biDirected component containing nodeName w.r.t the ancestral set of nodes inNodes - the nodes in the graph which are not part of biNodes but which are a parent of some node in biNodes.

---

getMixedGraph	<i>Get the corresponding mixed graph</i>
---------------	--

---

**Description**

Only works for graphs where the latent nodes are source nodes

**Usage**

```
getMixedGraph(this, ...)
```

```
## S3 method for class 'LatentDigraph'
getMixedGraph(this, ...)
```

**Arguments**

this	the LatentDigraph object
...	ignored

---

getParents	<i>Get getParents of nodes in a graph.</i>
------------	--

---

**Description**

Get the getParents of a collection of nodes in a graph g, the getParents DO include the input nodes themselves.

**Usage**

```
getParents(g, nodes)
```

**Arguments**

g	the graph (as an igraph).
nodes	the nodes in the graph of which to get the getParents.

**Value**

a sorted vector of all parent nodes.

---

getSiblings	<i>Get getSiblings of nodes in a graph.</i>
-------------	---

---

**Description**

Get the getSiblings of a collection of nodes in a graph g, the getSiblings DO include the input nodes themselves.

**Usage**

```
getSiblings(g, nodes)
```

**Arguments**

g	the graph (as an igraph).
nodes	the nodes in the graph of which to get the getSiblings.

**Value**

a sorted vector of all getSiblings of nodes.

---

getTrekSystem	<i>Determines if a trek system exists in the mixed graph.</i>
---------------	---

---

**Description**

Determines if a trek system exists in the mixed graph.

**Usage**

```
getTrekSystem(
  this,
  fromNodes,
  toNodes,
  avoidLeftNodes = integer(0),
  avoidRightNodes = integer(0),
  avoidLeftEdges = integer(0),
  avoidRightEdges = integer(0),
  ...
)

## S3 method for class 'LatentDigraphFixedOrder'
getTrekSystem(
  this,
  fromNodes,
```

```

    toNodes,
    avoidLeftNodes = integer(0),
    avoidRightNodes = integer(0),
    avoidLeftEdges = integer(0),
    avoidRightEdges = integer(0),
    ...
)

## S3 method for class 'LatentDigraph'
getTrekSystem(
  this,
  fromNodes,
  toNodes,
  avoidLeftNodes = integer(0),
  avoidRightNodes = integer(0),
  avoidLeftEdges = integer(0),
  avoidRightEdges = integer(0),
  ...
)

```

### Arguments

<code>this</code>	the graph object
<code>fromNodes</code>	the start nodes
<code>toNodes</code>	the end nodes
<code>avoidLeftNodes</code>	a collection of nodes to avoid on the left
<code>avoidRightNodes</code>	a collection of nodes to avoid on the right
<code>avoidLeftEdges</code>	a collection of edges between observed nodes in the graph that should not be used on any right hand side of any trek in the trek system.
<code>avoidRightEdges</code>	a collection of edges between observed nodes in the graph that should not be used on any right hand side of any trek in the trek system.
<code>...</code>	ignored

---

globalID

*Determines whether a mixed graph is globally identifiable.*

---

### Description

Uses the criterion in Theorem 2 of the paper by Drton, Foygel and Sullivant (2011) to determine whether a mixed graph is globally identifiable.

### Usage

```
globalID(graph)
```

**Arguments**

graph            a `MixedGraph` object representing the mixed graph.

**Value**

TRUE if the graph is globally identifiable, FALSE otherwise.

**References**

Drton, M., Barber, R. F., and Sullivan S. (2011). Half-Trek Criterion for Identifiability of Latent Variable Models. *Ann. Statist.* 39 (2011), no. 2, 865–886 <doi:10.1214/10-AOS859>.

---

graphID

*Identifiability of linear structural equation models.*

---

**Description**

NOTE: graphID has been deprecated, use `semID` instead.

This function checks global and generic identifiability of linear structural equation models. For generic identifiability the function checks a sufficient criterion as well as a necessary criterion but this check may be inconclusive.

**Usage**

```
graphID(
  L,
  O,
  output.type = "matrix",
  file.name = NULL,
  decomp.if.acyclic = TRUE,
  test.globalID = TRUE,
  test.genericID = TRUE,
  test.nonID = TRUE
)
```

**Arguments**

L            Adjacency matrix for the directed part of the path diagram/mixed graph; an edge pointing from  $i$  to  $j$  is encoded as  $L[i,j]=1$  and the lack of an edge between  $i$  and  $j$  is encoded as  $L[i,j]=0$ . There should be no directed self loops, i.e. no  $i$  such that  $L[i,i]=1$ .

O            Adjacency matrix for the bidirected part of the path diagram/mixed graph. Edges are encoded as for the L parameter. Again there should be no self loops. Also this matrix will be coerced to be symmetric so it is only necessary to specify an edge once, i.e. if  $O[i,j]=1$  you may, but are not required to, also have  $O[j,i]=1$ .

<code>output.type</code>	A character string indicating whether output is printed ('matrix'), saved to a file ('file'), or returned as a list ('list') for further processing in R.
<code>file.name</code>	A character string naming the output file.
<code>decomp.if.acyclic</code>	A logical value indicating whether an input graph that is acyclic is to be decomposed before applying identifiability criteria.
<code>test.globalID</code>	A logical value indicating whether or not global identifiability is checked.
<code>test.genericID</code>	A logical value indicating whether or not a sufficient condition for generic identifiability is checked.
<code>test.nonID</code>	A logical value indicating whether or not a condition implying generic non-identifiability is checked.

### Value

A list or printed matrix indicating the identifiability status of the linear SEM given by the input graph. Optionally the graph's components are listed.

With `output.type = 'list'`, the function returns a list of components for the graph. Each list entry is again a list that indicates first which nodes form the component and second whether the component forms a mixed graph that is acyclic. The next entries in the list show HTC-identifiable nodes, meaning nodes  $v$  for which the coefficients for all the directed edges pointing to  $v$  can be identified using the methods from Foygel et al. (2012). The HTC-identifiable nodes are listed in the order in which they are found by the recursive identification algorithm. The last three list entries are logical values that indicate whether or not the graph component is generically identifiable, globally identifiable or not identifiable; compare Drton et al. (2011) and Foygel et al. (2012). In the latter case the Jacobian of the parametrization does not have full rank.

With `output.type = 'matrix'`, a summary of the above information is printed.

```

---

graphID.ancestralID    *Determine generic identifiability of an acyclic mixed graph using ancestral decomposition.*

---

### Description

For an input, acyclic, mixed graph attempts to determine if the graph is generically identifiable using decomposition by ancestral subsets. See algorithm 1 of Drton and Weihs (2015).

### Usage

```
graphID.ancestralID(L, 0)
```

### Arguments

L	Adjacency matrix for the directed part of the path diagram/mixed graph; an edge pointing from $i$ to $j$ is encoded as $L[i,j]=1$ and the lack of an edge between $i$ and $j$ is encoded as $L[i,j]=0$ . There should be no directed self loops, i.e. no $i$ such that $L[i,i]=1$ .
O	Adjacency matrix for the bidirected part of the path diagram/mixed graph. Edges are encoded as for the L parameter. Again there should be no self loops. Also this matrix will be coerced to be symmetric so it is only necessary to specify an edge once, i.e. if $O[i,j]=1$ you may, but are not required to, also have $O[j,i]=1$ .

### Value

The vector of nodes that could be determined to be generically identifiable using the above algorithm.

### References

Drton, M. and Weihs, L. (2015) Generic Identifiability of Linear Structural Equation Models by Ancestor Decomposition. arXiv 1504.02992

---

graphID.decompose      *Determine generic identifiability by Tian Decomposition and HTC*

---

### Description

Split a graph into mixed Tian components and solve each separately using the HTC.

### Usage

```
graphID.decompose(
    L,
    O,
    decomp.if.acyclic = TRUE,
    test.globalID = TRUE,
    test.genericID = TRUE,
    test.nonID = TRUE
)
```

### Arguments

L	Adjacency matrix for the directed part of the path diagram/mixed graph; an edge pointing from i to j is encoded as $L[i,j]=1$ and the lack of an edge between i and j is encoded as $L[i,j]=0$ . There should be no directed self loops, i.e. no i such that $L[i,i]=1$ .
O	Adjacency matrix for the bidirected part of the path diagram/mixed graph. Edges are encoded as for the L parameter. Again there should be no self loops. Also this matrix will be coerced to be symmetric so it is only necessary to specify an edge once, i.e. if $O[i,j]=1$ you may, but are not required to, also have $O[j,i]=1$ .
decomp.if.acyclic	A logical value indicating whether an input graph that is acyclic is to be decomposed before applying identifiability criteria.
test.globalID	A logical value indicating whether or not global identifiability is checked.
test.genericID	A logical value indicating whether or not a sufficient condition for generic identifiability is checked.
test.nonID	A logical value indicating whether or not a condition implying generic non-identifiability is checked.

### Value

A list with two named components:

1. Components - a list of lists. Each list represents one mixed Tian component of the graph. Each list contains named components corresponding to which nodes are in the component and results of various tests of identifiability on the component (see the parameter descriptions).
2. Decomp - true if a decomposition occurred, false if not.

---

graphID.genericID      *Determine generic identifiability of a mixed graph.*

---

### Description

If the directed part of input graph is cyclic then will check for generic identifiability using the half-trek criterion. Otherwise will use the a slightly stronger version of the half-trek criterion using ancestor decompositions.

### Usage

graphID.genericID(L, 0)

### Arguments

- |   |  |
|---|--|
| L | Adjacency matrix for the directed part of the path diagram/mixed graph; an edge pointing from $i$ to $j$ is encoded as $L[i,j]=1$ and the lack of an edge between $i$ and $j$ is encoded as $L[i,j]=0$ . There should be no directed self loops, i.e. no $i$ such that $L[i,i]=1$ .  |
| 0 | Adjacency matrix for the bidirected part of the path diagram/mixed graph. Edges are encoded as for the L parameter. Again there should be no self loops. Also this matrix will be coerced to be symmetric so it is only necessary to specify an edge once, i.e. if $O[i,j]=1$ you may, but are not required to, also have $O[j,i]=1$ . |

### Value

The vector of nodes that could be determined to be generically identifiable.

### References

- Foygel, R., Draisma, J., and Drton, M. (2012) Half-trek criterion for generic identifiability of linear structural equation models. *Ann. Statist.* 40(3): 1682-1713.

---

graphID.htcID      *Determines if a mixed graph is HTC-identifiable.*

---

### Description

Uses the half-trek criterion of Foygel, Draisma, and Drton (2013) to check if an input mixed graph is generically identifiable.

### Usage

graphID.htcID(L, 0)

**Arguments**

- L Adjacency matrix for the directed part of the path diagram/mixed graph; an edge pointing from  $i$  to  $j$  is encoded as  $L[i,j]=1$  and the lack of an edge between  $i$  and  $j$  is encoded as  $L[i,j]=0$ . There should be no directed self loops, i.e. no  $i$  such that  $L[i,i]=1$ .
- O Adjacency matrix for the bidirected part of the path diagram/mixed graph. Edges are encoded as for the L parameter. Again there should be no self loops. Also this matrix will be coerced to be symmetric so it is only necessary to specify an edge once, i.e. if  $O[i,j]=1$  you may, but are not required to, also have  $O[j,i]=1$ .

**Value**

The vector of HTC-identifiable nodes.

**References**

Foygel, R., Draisma, J., and Drton, M. (2012) Half-trek criterion for generic identifiability of linear structural equation models. *Ann. Statist.* 40(3): 1682-1713.

---

graphID.main

*Helper function to handle a graph component.*

---

**Description**

Calls the other functions that determine identifiability status.

**Usage**

```
graphID.main(
  L,
  O,
  test.globalID = TRUE,
  test.genericID = TRUE,
  test.nonID = TRUE
)
```

**Arguments**

- L Adjacency matrix for the directed part of the path diagram/mixed graph; an edge pointing from  $i$  to  $j$  is encoded as  $L[i,j]=1$  and the lack of an edge between  $i$  and  $j$  is encoded as  $L[i,j]=0$ . There should be no directed self loops, i.e. no  $i$  such that  $L[i,i]=1$ .
- O Adjacency matrix for the bidirected part of the path diagram/mixed graph. Edges are encoded as for the L parameter. Again there should be no self loops. Also this matrix will be coerced to be symmetric so it is only necessary to specify an edge once, i.e. if  $O[i,j]=1$  you may, but are not required to, also have  $O[j,i]=1$ .

test.globalID	A logical value indicating whether or not global identifiability is checked.
test.genericID	A logical value indicating whether or not a sufficient condition for generic identifiability is checked.
test.nonID	A logical value indicating whether or not a condition implying generic non-identifiability is checked.

**Value**

A list containing named components of the results of various tests desired based on the input parameters.

---

graphID.nonHtcID	<i>Check for generic infinite-to-one via the half-trek criterion.</i>
------------------	---

---

**Description**

Checks if a mixed graph is infinite-to-one using the half-trek criterion presented by Foygel, Draisma, and Drton (2012).

**Usage**

```
graphID.nonHtcID(L, 0)
```

**Arguments**

L	Adjacency matrix for the directed part of the path diagram/mixed graph; an edge pointing from $i$ to $j$ is encoded as $L[i,j]=1$ and the lack of an edge between $i$ and $j$ is encoded as $L[i,j]=0$ . There should be no directed self loops, i.e. no $i$ such that $L[i,i]=1$ .
0	Adjacency matrix for the bidirected part of the path diagram/mixed graph. Edges are encoded as for the L parameter. Again there should be no self loops. Also this matrix will be coerced to be symmetric so it is only necessary to specify an edge once, i.e. if $O[i,j]=1$ you may, but are not required to, also have $O[j,i]=1$ .

**Value**

TRUE if the graph could be determined to be generically non-identifiable, FALSE if this test was inconclusive.

**References**

Foygel, R., Draisma, J., and Drton, M. (2012) Half-trek criterion for generic identifiability of linear structural equation models. *Ann. Statist.* 40(3): 1682-1713.

---

htcID *Determines which edges in a mixed graph are HTC-identifiable.*

---

### Description

Uses the half-trek criterion of Foygel, Draisma, and Drton (2012) determine which edges in a mixed graph are generically identifiable. Depending on your application it faster to use the [graphID.htcID](#) function instead of this one, this function has the advantage of returning additional information.

### Usage

```
htcID(mixedGraph, tianDecompose = T)
```

### Arguments

`mixedGraph` a [MixedGraph](#) object representing the L-SEM.  
`tianDecompose` TRUE or FALSE determining whether or not the Tian decomposition should be used before running the current generic identification algorithm. In general letting this be TRUE will make the algorithm faster and more powerful.

### Value

see the return value of [generalGenericID](#).

### References

Foygel, R., Draisma, J., and Drton, M. (2012) Half-trek criterion for generic identifiability of linear structural equation models. *Ann. Statist.* 40(3): 1682-1713.

Jin Tian. 2005. Identifying direct causal effects in linear models. In *Proceedings of the 20th national conference on Artificial intelligence - Volume 1 (AAAI'05)*, Anthony Cohn (Ed.), Vol. 1. AAAI Press 346-352.

---

htcIdentifyStep *Perform one iteration of HTC identification.*

---

### Description

A function that does one step through all the nodes in a mixed graph and tries to identify new edge coefficients using the existence of half-trek systems as described in Foygel, Draisma, Drton (2012).

### Usage

```
htcIdentifyStep(mixedGraph, unsolvedParents, solvedParents, identifier)
```

**Arguments**

- mixedGraph** a `MixedGraph` object representing the mixed graph.
- unsolvedParents** a list whose  $i$ th index is a vector of all the parents  $j$  of  $i$  in  $G$  which for which the edge  $j \rightarrow i$  is not yet known to be generically identifiable.
- solvedParents** the complement of `unsolvedParents`, a list whose  $i$ th index is a vector of all parents  $j$  of  $i$  for which the edge  $i \rightarrow j$  is known to be generically identifiable (perhaps by other algorithms).
- identifier** an identification function that must produce the identifications corresponding to those in solved parents. That is `identifier` should be a function taking a single argument `Sigma` (any generically generated covariance matrix corresponding to the mixed graph) and returns a list with two named arguments
- Lambda** denote the number of nodes in `mixedGraph` as  $n$ . Then `Lambda` is an  $n \times n$  matrix whose  $i, j$ th entry
1. equals 0 if  $i$  is not a parent of  $j$ ,
  2. equals NA if  $i$  is a parent of  $j$  but `identifier` cannot identify it generically,
  3. equals the (generically) unique value corresponding to the weight along the edge  $i \rightarrow j$  that was used to produce `Sigma`.
- Omega** just as `Lambda` but for the bidirected edges in the mixed graph such that if  $j$  is in `solvedParents[[i]]` we must have that `Lambda[j,i]` is not NA.

**Value**

a list with four components:

**identifiedEdges** a matrix  $r \times 2$  matrix where  $r$  is the number of edges that were identified by this function call and `identifiedEdges[i,1] -> identifiedEdges[i,2]` was the  $i$ th edge identified

**unsolvedParents** as the input argument but updated with any newly identified edges

**solvedParents** as the input argument but updated with any newly identified edges

**identifier** as the input argument but updated with any newly identified edges

**References**

Foygel, R., Draisma, J., and Drton, M. (2012) Half-trek criterion for generic identifiability of linear structural equation models. *Ann. Statist.* 40(3): 1682-1713

---

htr	<i>Get all HTR nodes from a set of nodes in a graph.</i>
-----	--

---

**Description**

Gets all vertices in a graph that are half-trek reachable from a set of nodes. **WARNING:** Often the half-trek reachable nodes from a vertex *v* are defined to not include the vertex *v* or its `getSiblings`. We **DO NOT** follow this convention, the returned set will include input nodes and their `getSiblings`.

**Usage**

```
htr(dG, bG, nodes)
```

**Arguments**

dG	a directed graph representing the directed part of the mixed graph.
bG	an undirected graph representing the undirected part of the mixed graph.
nodes	the nodes in the graph of which to get the HTR nodes.

**Value**

a sorted list of all half-trek reachable nodes.

---

htrFrom	<i>Half trek reachable nodes.</i>
---------	-----------------------------------

---

**Description**

Half trek reachable nodes.

**Usage**

```
htrFrom(this, nodes, ...)

## S3 method for class 'MixedGraph'
htrFrom(
  this,
  nodes,
  avoidLeftNodes = integer(0),
  avoidRightNodes = integer(0),
  ...
)
```

**Arguments**

this            the mixed graph object  
 nodes          the nodes from which to get all half-trek reachable nodes.  
 ...            ignored.  
 avoidLeftNodes a collection of nodes to avoid on the left  
 avoidRightNodes a collection of nodes to avoid on the right

**Value**

a vector of all nodes half-trek reachable from node.

---

inducedSubgraph	<i>Get the induced subgraph on a collection of nodes</i>
-----------------	--

---

**Description**

Get the induced subgraph on a collection of nodes

**Usage**

```

inducedSubgraph(this, nodes, ...)

## S3 method for class 'LatentDigraph'
inducedSubgraph(this, nodes, ...)

## S3 method for class 'MixedGraph'
inducedSubgraph(this, nodes, ...)

```

**Arguments**

this            the graph object  
 nodes          the nodes on which to create the induced subgraph.  
 ...            ignored.

---

isSibling	<i>Are two nodes siblings?</i>
-----------	--------------------------------

---

**Description**

Are two nodes siblings?

**Usage**

```
isSibling(this, node1, node2, ...)

## S3 method for class 'MixedGraph'
isSibling(this, node1, node2, ...)
```

**Arguments**

this	the mixed graph object
node1	a node
node2	a second node
...	ignored.

**Value**

TRUE if the nodes are siblings in the graph, FALSE otherwise

---

L	<i>Get directed adjacency matrix.</i>
---	---------------------------------------

---

**Description**

Get directed adjacency matrix.

**Usage**

```
L(this, ...)

## S3 method for class 'LatentDigraphFixedOrder'
L(this, ...)

## S3 method for class 'LatentDigraph'
L(this, ...)

## S3 method for class 'MixedGraph'
L(this, ...)
```

**Arguments**

`this`            the graph object  
`...`            ignored.

---

LatentDigraph            *Construct a LatentDigraph object*

---

**Description**

Creates an object representing a latent factor graph. The methods that are currently available to be used on the latent factor graph include

1. numObserved
2. numLatents
3. numNodes
4. toIn
5. toEx
6. L
7. observedNodes
8. latentNodes
9. parents
10. children
11. ancestors
12. descendants
13. trFrom
14. getTrekSystem
15. inducedSubgraph
16. stronglyConnectedComponent
17. plot
18. observedParents
19. getMixedGraph

see the individual function documentation for more information.

**Usage**

```
LatentDigraph(L = matrix(0,1,1),
              observedNodes = seq(1, length = nrow(L)),
              latentNodes = integer(0))
```

**Arguments**

L	see <a href="#">graphID</a> for the appropriate form of L.
observedNodes	a vector of positive integers representing the vertex numbers of the observed nodes. These will correspond, in order, to the first length(observedNodes) rows of L.
latentNodes	a vector of positive integers representing the vertex numbers of the latent nodes. These will correspond, in order, to the last length(latentNodes) rows of L.

**Value**

An object representing the LatentDigraph

---

LatentDigraphFixedOrder

*Construct LatentDigraphFixedOrder object*

---

**Description**

Creates an object representing a directed graph with some number of nodes which are latent (unobserved).

**Usage**

```
LatentDigraphFixedOrder(L = matrix(0,1,1), numObserved = nrow(L))
```

**Arguments**

L	see <a href="#">graphID</a> for the appropriate form of L. The first numObserved rows of L correspond to the observed nodes in the graph, all other nodes are considered unobserved.
numObserved	a non-negative integer representing the number of observed nodes in the graph.

**Value**

An object representing the LatentDigraphFixedOrder

---

latentDigraphHasSimpleNumbering

*Checks that a LatentDigraph has appropriate node numbering*

---

### Description

Checks that the input latent digraph has nodes numbered from 1 to latentDigraph\$numObserved()+latentDigraph\$numLatents. The first latentDigraph\$numObserved() nodes correspond to the observed nodes in the graph, all other nodes are considered unobserved. Throws an error if this is not true.

### Usage

```
latentDigraphHasSimpleNumbering(graph)
```

### Arguments

graph	a <a href="#">LatentDigraph</a> object representing the latent-factor graph. All latent nodes in this graph should be source nodes (i.e. have no parents).
-------	--

---

latentNodes

*Get all latent nodes in the graph.*

---

### Description

Get all latent nodes in the graph.

### Usage

```
latentNodes(this, ...)
```

```
## S3 method for class 'LatentDigraph'
latentNodes(this, ...)
```

### Arguments

this	the graph object
...	ignored

---

lfhtcID	<i>Determines which edges in a latent digraph are LF-HTC-identifiable.</i>
---------	--

---

### Description

Uses the latent-factor half-trek criterion to determine which edges in a latent digraph are generically identifiable.

### Usage

```
lfhtcID(graph)
```

### Arguments

`graph` a [LatentDigraph](#) object representing the latent-factor graph. All latent nodes in this graph should be source nodes (i.e. have no parents).

### Value

returns a list with 8 components:

`solvedParents` a list whose  $i$ th element contains a vector containing the subsets of parents of node  $i$  for which the edge  $j \rightarrow i$  could be shown to be generically identifiable.

`unsolvedParents` as for `solvedParents` but for the unsolved parents.

`identifier` a function that takes a (generic) covariance matrix corresponding to the graph and identifies the edges parameters from `solvedParents` and `solvedSiblings`. See [htcIdentifyStep](#) for a more in-depth discussion of identifier functions.

`graph` a latent digraph object of the graph.

`call` the call made to this function.

`activeFroms` list. If node  $i$  is solved then the  $i$ th index is a vector containing the nodes  $Y$  otherwise it is empty.

`Zs` list. If node  $i$  is solved then the  $i$ th index is a vector containing the nodes  $Z$  otherwise it is empty.

`Ls` list. If node  $i$  is solved then the  $i$ th index is a vector containing the nodes  $L$  otherwise it is empty.

---

lfhtcIdentifyStep      *Perform one iteration of latent-factor HTC identification.*

---

### Description

A function that does one step through all the nodes in a latent-factor graph and tries to identify new edge coefficients using the existence of latent-factor half-trek systems.

### Usage

```
lfhtcIdentifyStep(
  graph,
  unsolvedParents,
  solvedParents,
  activeFroms,
  Zs,
  Ls,
  identifier,
  subsetSizeControl = Inf
)
```

### Arguments

graph	a <a href="#">LatentDigraph</a> object representing the latent-factor graph. All latent nodes in this graph should be source nodes (i.e. have no parents).
unsolvedParents	a list whose <i>i</i> th index is a vector of all the parents <i>j</i> of <i>i</i> in the graph which for which the edge <i>j</i> -> <i>i</i> is not yet known to be generically identifiable.
solvedParents	the complement of <code>unsolvedParents</code> , a list whose <i>i</i> th index is a vector of all parents <i>j</i> of <i>i</i> for which the edge <i>i</i> -> <i>j</i> is known to be generically identifiable (perhaps by other algorithms).
activeFroms	list. If node <i>i</i> is solved then the <i>i</i> th index is a vector containing the nodes <i>Y</i> otherwise it is empty.
Zs	list. If node <i>i</i> is solved then the <i>i</i> th index is a vector containing the nodes <i>Z</i> otherwise it is empty.
Ls	list. If node <i>i</i> is solved then the <i>i</i> th index is a vector containing the nodes <i>Z</i> otherwise it is empty.
identifier	an identification function that must produce the identifications corresponding to those in solved parents. That is <code>identifier</code> should be a function taking a single argument <code>Sigma</code> (any generically generated covariance matrix corresponding to the latent-factor graph) and returns a list with two named arguments
subsetSizeControl	the largest subset of latent nodes to consider.

**Value**

a list with four components:

`identifiedEdges` a matrix  $r \times 2$  matrix where  $r$  is the number of edges that were identified by this function call and `identifiedEdges[i,1] -> identifiedEdges[i,2]` was the  $i$ th edge identified

`unsolvedParents` as the input argument but updated with any newly identified edges

`solvedParents` as the input argument but updated with any newly identified edges

`identifier` as the input argument but updated with any newly identified edges

`activeFroms` as the input argument but updated with any newly solved node

`Zs` as the input argument but updated with any newly solved node

`Ls` as the input argument but updated with any newly solved node

---

mID

*Check M-Identifiability.*

---

**Description**

Check M-Identifiability.

**Usage**

```
mID(lambda, maxCard = length(observedNodes))
```

**Arguments**

`lambda` adjacency matrix with number of cols = number of latent nodes, number of rows = number of observed nodes

`maxCard` (optional) maximum size of set  $W$

**Value**

a list consisting of a Boolean, whether the graph is sign-identifiable and if yes, a list consisting of the sets

**References**

MixedGraph

*Construct MixedGraph object***Description**

Creates an object representing a mixed graph. The methods that are currently available to be used on the mixed graph include

1. ancestors
2. descendants
3. parents
4. siblings
5. isSibling
6. htrFrom
7. trFrom
8. getHalfTrekSystem
9. getTrekSystem
10. inducedSubgraph
11. L
12. O
13. nodes
14. numNodes
15. stronglyConnectedComponent
16. tianComponent
17. tianDecompose

see the individual function documentation for more information.

**Usage**

```
MixedGraph(
  L = matrix(0, 1, 1),
  O = matrix(0, 1, 1),
  vertexNums = seq(1, length = nrow(L))
)
```

**Arguments**

- |            |  |
|------------|--|
| L          | see <a href="#">graphID</a> for the appropriate form of L.   |
| O          | as for L.  |
| vertexNums | the labeling of the vertices in the graph in the order of the rows of L and O. Labels must be positive integers. |

**Value**

An object representing the MixedGraph

---

`mixedGraphHasSimpleNumbering`

*Checks that a MixedGraph has appropriate node numbering*

---

**Description**

Checks that the input mixed graph has vertices are numbered from 1 to `mixedGraph$numNodes()`.  
Throws an error if they are not.

**Usage**

`mixedGraphHasSimpleNumbering(mixedGraph)`

**Arguments**

`mixedGraph`      the mixed graph object

---

`nodes`              *Get all nodes in the graph.*

---

**Description**

Get all nodes in the graph.

**Usage**

`nodes(this, ...)`

## S3 method for class 'MixedGraph'  
`nodes(this, ...)`

**Arguments**

`this`              the mixed graph object  
`...`              ignored.

---

numLatents	<i>Number of latent nodes in the graph.</i>
------------	---

---

**Description**

Number of latent nodes in the graph.

**Usage**

```
numLatents(this, ...)

## S3 method for class 'LatentDigraphFixedOrder'
numLatents(this, ...)

## S3 method for class 'LatentDigraph'
numLatents(this, ...)
```

**Arguments**

this	the graph object
...	ignored

---

numNodes	<i>Number of nodes in the graph.</i>
----------	--------------------------------------

---

**Description**

Number of nodes in the graph.

**Usage**

```
numNodes(this, ...)

observedParents(this, nodes, ...)
```

```
## S3 method for class 'LatentDigraph'  
observedParents(this, nodes, ...)
```

**Arguments**

this	the graph object
nodes	the nodes on which to get the observed parents
...	ignored

---

parents	<i>All parents of a collection of nodes.</i>
---------	--

---

**Description**

Returns all parents of the collection (does not necessarily include the input nodes themselves unless they are parents of one another).

**Usage**

```
parents(this, nodes, ...)

## S3 method for class 'LatentDigraphFixedOrder'
parents(this, nodes, includeObserved = T, includeLatents = T, ...)

## S3 method for class 'LatentDigraph'
parents(this, nodes, includeObserved = T, includeLatents = T, ...)

## S3 method for class 'MixedGraph'
parents(this, nodes, ...)
```

**Arguments**

this	the graph object.
nodes	nodes the nodes of which to find the parents.
...	ignored.
includeObserved	if TRUE includes observed nodes in the returned set.
includeLatents	if TRUE includes latent nodes in the returned set.

**Value**

the observed parents.

---

plot.LatentDigraph	<i>Plots the latent digraph</i>
--------------------	---------------------------------

---

**Description**

Plots the latent digraph  
Plots the mixed graph

**Usage**

```
## S3 method for class 'LatentDigraph'
plot(x, ...)

## S3 method for class 'MixedGraph'
plot(x, ...)
```

**Arguments**

x                    the mixed graph object  
 ...                 additional plotting arguments. Currently ignored.

---

plotLatentDigraph     *Plot a latent factor graph*

---

**Description**

Given an adjacency matrix representing the directed edges in a latent factor graph, plots a representation of the graph. The latent nodes should come last in L and the vertex labels should only be given for the observed nodes.

**Usage**

```
plotLatentDigraph(L, observedNodes, latentNodes, main = "")
```

**Arguments**

L                    Adjacency matrix for the directed part of the path diagram/mixed graph; an edge pointing from i to j is encoded as  $L[i,j]=1$  and the lack of an edge between i and j is encoded as  $L[i,j]=0$ . There should be no directed self loops, i.e. no i such that  $L[i,i]=1$ .

observedNodes     a vector of positive integers representing the vertex numbers of the observed nodes. These will correspond, in order, to the first  $\text{length}(\text{observedNodes})$  rows of L.

latentNodes        a vector of positive integers representing the vertex numbers of the latent nodes. These will correspond, in order, to the last  $\text{length}(\text{latentNodes})$  rows of L.

main                the plot title.

**Value**

An object representing the LatentDigraph

---

plotMixedGraph	<i>Plot a mixed graph</i>
----------------	---------------------------

---

### Description

Given adjacency matrices representing the directed and bidirected portions of a mixed graph, plots a representation of the graph.

### Usage

```
plotMixedGraph(L, O, main = "", vertexLabels = 1:nrow(L))
```

### Arguments

L	Adjacency matrix for the directed part of the path diagram/mixed graph; an edge pointing from i to j is encoded as $L[i,j]=1$ and the lack of an edge between i and j is encoded as $L[i,j]=0$ . There should be no directed self loops, i.e. no i such that $L[i,i]=1$ .
O	Adjacency matrix for the bidirected part of the path diagram/mixed graph. Edges are encoded as for the L parameter. Again there should be no self loops. Also this matrix will be coerced to be symmetric so it is only necessary to specify an edge once, i.e. if $O[i,j]=1$ you may, but are not required to, also have $O[j,i]=1$ .
main	the plot title.
vertexLabels	labels to use for the vertices.

---

print.extmIDresult	<i>Prints a extmIDresult object</i>
--------------------	-------------------------------------

---

### Description

Prints a extmIDresult object as returned by `extmID`. Invisibly returns its argument via `invisible(x)` as most print functions do.

### Usage

```
## S3 method for class 'extmIDresult'
print(x, ...)
```

### Arguments

x	the extmIDresult object
...	optional parameters, currently unused.

---

`print.GenericIDResult` *Prints a GenericIDResult object*

---

### **Description**

Prints a GenericIDResult object as returned by `generalGenericID`. Invisibly returns its argument via `invisible(x)` as most print functions do.

### **Usage**

```
## S3 method for class 'GenericIDResult'  
print(x, ...)
```

### **Arguments**

<code>x</code>	the GenericIDResult object
<code>...</code>	optional parameters, currently unused.

---

`print.LfhtcIDResult` *Prints a LfhtcIDResult object*

---

### **Description**

Prints a LfhtcIDResult object as returned by `lfhtcID`. Invisibly returns its argument via `invisible(x)` as most print functions do.

### **Usage**

```
## S3 method for class 'LfhtcIDResult'  
print(x, ...)
```

### **Arguments**

<code>x</code>	the LfhtcIDResult object
<code>...</code>	optional parameters, currently unused.

---

print.mIDresult	<i>Prints a mIDresult object</i>
-----------------	----------------------------------

---

### Description

Prints a mIDresult object as returned by `mID`. Invisibly returns its argument via `invisible(x)` as most print functions do.

### Usage

```
## S3 method for class 'mIDresult'  
print(x, ...)
```

### Arguments

x	the mIDresult object
...	optional parameters, currently unused.

---

print.SEMIDResult	<i>Prints a SEMIDResult object</i>
-------------------	------------------------------------

---

### Description

Prints a SEMIDResult object as returned by `semID`. Invisibly returns its argument via `invisible(x)` as most print functions do.

### Usage

```
## S3 method for class 'SEMIDResult'  
print(x, ...)
```

### Arguments

x	the SEMIDResult object
...	optional parameters, currently unused.

---

print.ZUTAResult	<i>Prints a ZUTAResult object</i>
------------------	-----------------------------------

---

### Description

Prints a ZUTAResult object as returned by [ZUTA](#). Invisibly returns its argument via [invisible\(x\)](#) as most print functions do.

### Usage

```
## S3 method for class 'ZUTAResult'
print(x, ...)
```

### Arguments

x	the ZUTAResult object
...	optional parameters, currently unused.

---

semID	<i>Identifiability of linear structural equation models.</i>
-------	--

---

### Description

This function can be used to check global and generic identifiability of linear structural equation models (L-SEMs). In particular, this function takes a [MixedGraph](#) object corresponding to the L-SEM and checks different conditions known for global and generic identifiability.

### Usage

```
semID(
  mixedGraph,
  testGlobalID = TRUE,
  testGenericNonID = TRUE,
  genericIdStepFunctions = list(htcIdentifyStep),
  tianDecompose = TRUE
)
```

### Arguments

mixedGraph	a <a href="#">MixedGraph</a> object representing the L-SEM.
testGlobalID	TRUE or FALSE if the graph should be tested for global identifiability. This uses the <a href="#">globalID</a> function.

testGenericNonID	TRUE or FALSE if the graph should be tested for generic non-identifiability, that is, if for every generic choice of parameters for the L-SEM there are infinitely many other choices that lead to the same covariance matrix. This currently uses the <code>graphID.nonHtcID</code> function.
genericIdStepFunctions	a list of the generic identifier step functions that should be used for testing generic identifiability. See <code>generalGenericID</code> for a discussion of such functions. If this list is empty then generic identifiability is not tested. By default this will (only) run the half-trek criterion (see <code>htcIdentifyStep</code> ) for generic identifiability.
tianDecompose	TRUE or FALSE if the mixed graph should be Tian decomposed before running the identification algorithms (when appropriate). In general letting this be TRUE will make the algorithm faster and more powerful. Note that this is a version of the Tian decomposition that works also with cyclic graphs.

### Value

returns an object of class 'SEMIDResult,' this object is just a list with 6 components:

`isGlobalID` If `testGlobalID == TRUE`, then TRUE or FALSE if the graph is globally identifiable. If `testGlobalID == FALSE` then NA.

`isGenericNonID` If `testGenericNonID == TRUE`, then TRUE if the graph is generically non-identifiable or FALSE the test is inconclusive. If `testGenericNonID == FALSE` then NA.

`genericIDResult` If `length(genericIdStepFunctions) != 0` then a `GenericIDResult` object as returned by `generalGenericID`. Otherwise a list of length 0.

`mixedGraph` the inputted mixed graph object.

`tianDecompose` the argument `tianDecompose`.

`call` the call made to this function.

### Examples

```
## Not run:
L = t(matrix(
  c(0, 1, 0, 0, 0,
    0, 0, 1, 0, 0,
    0, 0, 0, 1, 0,
    0, 0, 0, 0, 1,
    0, 0, 0, 0, 0), 5, 5))
O = t(matrix(
  c(0, 0, 1, 1, 0,
    0, 0, 0, 1, 1,
    0, 0, 0, 0, 0,
    0, 0, 0, 0, 0,
    0, 0, 0, 0, 0), 5, 5))
O = O + t(O)
graph = MixedGraph(L,O)
semID(graph)
```

```
## Examples from Foygel, Draisma & Drton (2012)
demo(SEMID)

## End(Not run)
```

---

siblings	<i>All siblings of a collection of nodes</i>
----------	--

---

### Description

All siblings of a collection of nodes

### Usage

```
siblings(this, nodes, ...)

## S3 method for class 'MixedGraph'
siblings(this, nodes, ...)
```

### Arguments

this	the mixed graph object
nodes	a vector of nodes of which to find the siblings.
...	ignored.

### Value

a vector of all of the siblings.

---

stronglyConnectedComponent	<i>Strongly connected component</i>
----------------------------	-------------------------------------

---

### Description

Get the strongly connected component for a node *i* in the graph the graph.

**Usage**

```
stronglyConnectedComponent(this, node, ...)

## S3 method for class 'LatentDigraphFixedOrder'
stronglyConnectedComponent(this, node, ...)

## S3 method for class 'LatentDigraph'
stronglyConnectedComponent(this, node, ...)

## S3 method for class 'MixedGraph'
stronglyConnectedComponent(this, node, ...)
```

**Arguments**

<code>this</code>	the graph object
<code>node</code>	the node for which to get the strongly connected component.
<code>...</code>	ignored.

---

<code>subsetsOfSize</code>	<i>Returns all subsets of a certain size</i>
----------------------------	--

---

**Description**

For an input vector `x`, returns in a list, the collection of all subsets of `x` of size `k`.

**Usage**

```
subsetsOfSize(x, k)
```

**Arguments**

<code>x</code>	a vector from which to get subsets
<code>k</code>	the size of the subsets returned

**Value**

a list of all subsets of `x` of a given size `k`

---

tianComponent	<i>Returns the Tian c-component of a node</i>
---------------	---

---

**Description**

Returns the Tian c-component of a node

**Usage**

```
tianComponent(this, node)

## S3 method for class 'MixedGraph'
tianComponent(this, node)
```

**Arguments**

this	the mixed graph object
node	the node for which to return its c-component

---

tianDecompose	<i>Performs the tian decomposition on the mixed graph</i>
---------------	---

---

**Description**

Uses the Tian decomposition to break the mixed graph into c-components. These c-components are slightly different than those from Tian (2005) in that if they graph is not acyclic the bidirected components are combined whenever they are connected by a directed loop.

**Usage**

```
tianDecompose(this)

## S3 method for class 'MixedGraph'
tianDecompose(this)
```

**Arguments**

this	the mixed graph object
------	------------------------

---

tianIdentifier	<i>Identifies components in a tian decomposition</i>
----------------	--

---

**Description**

Creates an identification function which combines the identification functions created on a collection of c-components into a identification for the full mixed graph.

**Usage**

```
tianIdentifier(idFuncs, cComponents)
```

**Arguments**

idFuncs	a list of identifier functions for the c-components
cComponents	the c-components of the mixed graph as returned by <a href="#">tianDecompose</a> .

**Value**

a new identifier function

---

tianSigmaForComponent	<i>Globally identify the covariance matrix of a C-component</i>
-----------------------	---

---

**Description**

The Tian decomposition of a mixed graph G allows one to globally identify the covariance matrices Sigma' of special subgraphs of G called c-components. This function takes the covariance matrix Sigma corresponding to G and a collection of node sets which specify the c-component, and returns the Sigma' corresponding to the c-component.

**Usage**

```
tianSigmaForComponent(Sigma, internal, incoming, topOrder)
```

**Arguments**

Sigma	the covariance matrix for the mixed graph G
internal	an integer vector corresponding to the vertices of the C-component that are in the bidirected equivalence classes (if the graph is not-acyclic then these equivalence classes must be enlarged by combining two bidirected components if there are two vertices, one in each component, that are simultaneously on the same directed cycle).
incoming	the parents of vertices in internal that are not in the set internal themselves
topOrder	a topological ordering of c(internal, incoming) with respect to the graph G. For vertices in a strongly connected component the ordering is allowed to be arbitrary.

**Value**

the new Sigma corresponding to the c-component

---

toEx	<i>Transforms a vector of node indices in the internal rep. into external numbering</i>
------	---

---

**Description**

Transforms a vector of node indices in the internal rep. into external numbering

**Usage**

```
toEx(this, nodes, ...)

## S3 method for class 'LatentDigraph'
toEx(this, nodes, ...)

## S3 method for class 'MixedGraph'
toEx(this, nodes, ...)
```

**Arguments**

this	the graph object
nodes	the nodes to transform
...	ignored

---

toIn	<i>Transforms a vector of given node indices into their internal numbering</i>
------	--

---

**Description**

Transforms a vector of given node indices into their internal numbering

**Usage**

```
toIn(this, nodes, ...)

## S3 method for class 'LatentDigraph'
toIn(this, nodes, ...)

## S3 method for class 'MixedGraph'
toIn(this, nodes, ...)
```

**Arguments**

this	the graph object
nodes	the nodes to transform
...	ignored

---

trekSeparationIdentifyStep

*Perform one iteration of trek separation identification.*

---

**Description**

A function that does one step through all the nodes in a mixed graph and tries to identify new edge coefficients using trek-separation as described in Weihs, Robeva, Robinson, et al. (2017).

**Usage**

```
trekSeparationIdentifyStep(
  mixedGraph,
  unsolvedParents,
  solvedParents,
  identifier,
  maxSubsetSize = 3
)
```

**Arguments**

mixedGraph	a <b>MixedGraph</b> object representing the mixed graph.
unsolvedParents	a list whose <i>i</i> th index is a vector of all the parents <i>j</i> of <i>i</i> in <i>G</i> which for which the edge <i>j</i> -> <i>i</i> is not yet known to be generically identifiable.
solvedParents	the complement of <i>unsolvedParents</i> , a list whose <i>i</i> th index is a vector of all parents <i>j</i> of <i>i</i> for which the edge <i>i</i> -> <i>j</i> is known to be generically identifiable (perhaps by other algorithms).
identifier	an identification function that must produce the identifications corresponding to those in <i>solvedParents</i> . That is <i>identifier</i> should be a function taking a single argument <i>Sigma</i> (any generically generated covariance matrix corresponding to the mixed graph) and returns a list with two named arguments  <b>Lambda</b> denote the number of nodes in <i>mixedGraph</i> as <i>n</i> . Then <i>Lambda</i> is an <i>n</i> x <i>n</i> matrix whose <i>i,j</i> th entry <ol style="list-style-type: none"> <li>1. equals 0 if <i>i</i> is not a parent of <i>j</i>,</li> <li>2. equals NA if <i>i</i> is a parent of <i>j</i> but <i>identifier</i> cannot identify it generically,</li> <li>3. equals the (generically) unique value corresponding to the weight along the edge <i>i</i>-&gt;<i>j</i> that was used to produce <i>Sigma</i>.</li> </ol>

**Omega** just as Lambda but for the bidirected edges in the mixed graph such that if  $j$  is in `solvedParents[[i]]` we must have that `Lambda[j,i]` is not NA.

`maxSubsetSize` a positive integer which controls the maximum subset size considered in the trek-separation identification algorithm. Making this parameter smaller means the algorithm will be faster but less exhaustive (and hence less powerful).

### Value

see the return of [htcIdentifyStep](#).

---

<code>trFrom</code>	<i>Trek reachable nodes.</i>
---------------------	------------------------------

---

### Description

Gets all nodes that are trek reachable from a collection of nodes.

### Usage

```
trFrom(this, nodes, ...)
```

```
## S3 method for class 'LatentDigraphFixedOrder'
trFrom(
  this,
  nodes,
  avoidLeftNodes = integer(0),
  avoidRightNodes = integer(0),
  includeObserved = T,
  includeLatents = T,
  ...
)
```

```
## S3 method for class 'LatentDigraph'
trFrom(
  this,
  nodes,
  avoidLeftNodes = integer(0),
  avoidRightNodes = integer(0),
  includeObserved = T,
  includeLatents = T,
  ...
)
```

```
## S3 method for class 'MixedGraph'
trFrom(
  this,
```

```

    nodes,
    avoidLeftNodes = integer(0),
    avoidRightNodes = integer(0),
    ...
)

```

### Arguments

<code>this</code>	the graph object
<code>nodes</code>	the nodes from which to find trek-reachable nodes.
<code>...</code>	ignored.
<code>avoidLeftNodes</code>	a collection of nodes to avoid on the left
<code>avoidRightNodes</code>	a collection of nodes to avoid on the right
<code>includeObserved</code>	if TRUE includes observed nodes in the returned set.
<code>includeLatents</code>	if TRUE includes latent nodes in the returned set.

---

`updateEdgeCapacities` *Update edge capacities.*

---

### Description

Update edge capacities.

### Usage

```
updateEdgeCapacities(this, edges, newCaps)
```

```
## S3 method for class 'FlowGraph'
updateEdgeCapacities(this, edges, newCaps)
```

### Arguments

<code>this</code>	the flow graph object
<code>edges</code>	the vertices to update (as a 2xr matrix with ith column corresponding to the edge edges[1,i]->edges[2,i].
<code>newCaps</code>	the new capacities for the edges

updateVertexCapacities

*Update vertex capacities.*

---

### **Description**

Update vertex capacities.

### **Usage**

```
updateVertexCapacities(this, vertices, newCaps)
```

```
## S3 method for class 'FlowGraph'
```

```
updateVertexCapacities(this, vertices, newCaps)
```

### **Arguments**

this	the flow graph object
vertices	the vertices to update.
newCaps	the new capacities for the vertices.

---

validateLatentNodesAreSources

*A helper function to validate that latent nodes in a LatentDigraph are sources.*

---

### **Description**

Produces an error if not all latent nodes are sources.

### **Usage**

```
validateLatentNodesAreSources(graph)
```

### **Arguments**

graph	the LatentDigraph
-------	-------------------

---

validateMatrices      *A helper function to validate input matrices.*

---

**Description**

This helper function validates that the two input matrices, L and O, are of the appropriate form to be interpreted by the other functions. In particular they should be square matrices of 1's and 0's with all 0's along their diagonals. We do not require O to be symmetric here.

**Usage**

```
validateMatrices(L, O)
```

**Arguments**

L	See above description.
O	See above description.

**Value**

This function has no return value.

---

validateMatrix      *A helper function to validate an input matrix.*

---

**Description**

This helper function validates that an input matrix, L, is of the the appropriate form to be interpreted by the other functions. In particular it should be square matrix of 1's and 0's with all 0's along its diagonal. If any of the above conditions is not met, this function will throw an error.

**Usage**

```
validateMatrix(L)
```

**Arguments**

L	See above description.
---	------------------------

**Value**

No return value

---

validateNodes	<i>A helper function to validate if input nodes are valid.</i>
---------------	--

---

**Description**

Produces an error if outside bounds.

**Usage**

```
validateNodes(nodes, numNodes)
```

**Arguments**

nodes	the input nodes, expected to be from the collection 1:(number of nodes in the graph)
numNodes	the number of observed nodes in the graph.

---

validateVarArgsEmpty	<i>A helper function to validate that there are no variable arguments</i>
----------------------	---

---

**Description**

Produces an error if there are variable arguments.

**Usage**

```
validateVarArgsEmpty(...)
```

**Arguments**

...	the variable arguments
-----	------------------------

---

ZUTA

*Check the Zero Upper Triangular Assumption*

---

**Description**

Check the Zero Upper Triangular Assumption

**Usage**

ZUTA(lambda)

**Arguments**

lambda            adjacency matrix with number of cols = number of latent nodes, number of rows  
                         = number of observed nodes

**Value**

a Boolean, whether the graph fulfills ZUTA

**References**
