

# Package ‘np’

January 29, 2026

**Version** 0.60-19

**Date** 2026-01-29

**Imports** boot, cubature, methods, quadprog, quantreg, stats

**Suggests** crs, MASS, logspline, ks

**Title** Nonparametric Kernel Smoothing Methods for Mixed Data Types

**Maintainer** Jeffrey S. Racine <racinej@mcmaster.ca>

**Description** Nonparametric (and semiparametric) kernel methods that seamlessly handle a mix of continuous, unordered, and ordered factor data types. We would like to gratefully acknowledge support from the Natural Sciences and Engineering Research Council of Canada (NSERC, <<https://www.nserc-crsng.gc.ca/>>), the Social Sciences and Humanities Research Council of Canada (SSHRC, <<https://www.sshrc-crsh.gc.ca/>>), and the Shared Hierarchical Academic Research Computing Network (SHARCNET, <<https://sharcnet.ca/>>). We would also like to acknowledge the contributions of the GNU GSL authors. In particular, we adapt the GNU GSL B-spline routine `gsl_bspline.c` adding automated support for quantile knots (in addition to uniform knots), providing missing functionality for derivatives, and for extending the splines beyond their endpoints.

b.star	<i>Compute Optimal Block Length for Stationary and Circular Bootstrap</i>
--------	---

---

## Description

b.star is a function which computes the optimal block length for the continuous variable data using the method described in Patton, Politis and White (2009).

## Usage

```
b.star(data,
      Kn = NULL,
      mmax= NULL,
      Bmax = NULL,
      c = NULL,
      round = FALSE)
```

## Arguments

data	data, an $n \times k$ matrix, each column being a data series.
Kn	See footnote c, page 59, Politis and White (2004). Defaults to $\text{ceiling}(\log_{10}(n))$ .
mmax	See Politis and White (2004). Defaults to $\text{ceiling}(\sqrt{n}) + Kn$ .
Bmax	See Politis and White (2004). Defaults to $\text{ceiling}(\min(3 \cdot \sqrt{n}, n/3))$ .
c	See Politis and White (2004). Defaults to $\text{qnorm}(0.975)$ .
round	whether to round the result or not. Defaults to FALSE.

## Details

b.star is a function which computes optimal block lengths for the stationary and circular bootstraps. This allows the use of tsboot from the **boot** package to be fully automatic by using the output from b.star as an input to the argument `l =` in tsboot. See below for an example.

## Value

A  $k \times 2$  matrix of optimal bootstrap block lengths computed from data for the stationary bootstrap and circular bootstrap (column 1 is for the stationary bootstrap, column 2 the circular).

## Author(s)

Tristen Hayfield <tristen.hayfield@gmail.com>, Jeffrey S. Racine <racinej@mcmaster.ca>

## Examples

```
set.seed(12345)

# Function to generate an AR(1) series

ar.series <- function(phi,epsilon) {
  n <- length(epsilon)
  series <- numeric(n)
  series[1] <- epsilon[1]/(1-phi)
  for(i in 2:n) {
    series[i] <- phi*series[i-1] + epsilon[i]
  }
  return(series)
}

yt <- ar.series(0.1,rnorm(10000))
b.star(yt,round=TRUE)

yt <- ar.series(0.9,rnorm(10000))
b.star(yt,round=TRUE)
```

cps71

*Canadian High School Graduate Earnings*

---

## Description

Canadian cross-section wage data consisting of a random sample taken from the 1971 Canadian Census Public Use Tapes for male individuals having common education (grade 13). There are 205 observations in total.

## Usage

```
data("cps71")
```

## Format

A data frame with 2 columns, and 205 rows.

**logwage** the first column, of type numeric

**age** the second column, of type integer

**Source**

Aman Ullah

**References**

Pagan, A. and A. Ullah (1999), *Nonparametric Econometrics*, Cambridge University Press.

**Examples**

```
data("cps71")
attach(cps71)

plot(age, logwage, xlab="Age", ylab="log(wage)")

detach(cps71)
```

---

Engel95

---

1995 British Family Expenditure Survey

---

**Description**

British cross-section data consisting of a random sample taken from the British Family Expenditure Survey for 1995. The households consist of married couples with an employed head-of-household between the ages of 25 and 55 years. There are 1655 household-level observations in total.

**Usage**

```
data("Engel95")
```

**Format**

A data frame with 10 columns, and 1655 rows.

**food** expenditure share on food, of type numeric  
**catering** expenditure share on catering, of type numeric  
**alcohol** expenditure share on alcohol, of type numeric  
**fuel** expenditure share on fuel, of type numeric  
**motor** expenditure share on motor, of type numeric  
**fares** expenditure share on fares, of type numeric  
**leisure** expenditure share on leisure, of type numeric  
**logexp** logarithm of total expenditure, of type numeric  
**logwages** logarithm of total earnings, of type numeric  
**nkids** number of children, of type numeric

       col=c("blue", "red"),
       lwd=c(2, 2))

## End(Not run)

```

gradients

*Extract Gradients***Description**

gradients is a generic function which extracts gradients from objects.

**Usage**

```

gradients(x, ...)

## S3 method for class 'condensity'
gradients(x, errors = FALSE, ...)

## S3 method for class 'condistribution'
gradients(x, errors = FALSE, ...)

## S3 method for class 'npregression'
gradients(x, errors = FALSE, ...)

## S3 method for class 'qregression'
gradients(x, errors = FALSE, ...)

## S3 method for class 'singleindex'
gradients(x, errors = FALSE, ...)

```

**Arguments**

x	an object for which the extraction of gradients is meaningful.
...	other arguments.
errors	a logical value specifying whether or not standard errors of gradients are desired. Defaults to FALSE.

**Details**

This function provides a generic interface for extraction of gradients from objects.

**Value**

Gradients extracted from the model object `x`.

**Note**

This method currently only supports objects from the [np](#) library.

**Author(s)**

Tristen Hayfield <tristen.hayfield@gmail.com>, Jeffrey S. Racine <racinej@mcmaster.ca>

**References**

See the references for the method being interrogated via [gradients](#) in the appropriate help file. For example, for the particulars of the gradients for nonparametric regression see the references in [npreg](#)

**See Also**

[fitted](#), [residuals](#), [coef](#), and [se](#), for related methods; [np](#) for supported objects.

**Examples**

```
x <- runif(10)
y <- x + rnorm(10, sd = 0.1)
gradients(npreg(y~x, gradients=TRUE))
```

---

Italy

*Italian GDP Panel*

---

**Description**

Italian GDP growth panel for 21 regions covering the period 1951-1998 (millions of Lire, 1990=base). There are 1008 observations in total.

**Usage**

```
data("Italy")
```

**Format**

A data frame with 2 columns, and 1008 rows.

**year** the first column, of type ordered

**gdp** the second column, of type numeric: millions of Lire, 1990=base

## Source

Giovanni Baiocchi

## References

np

---

*Nonparametric Kernel Smoothing Methods for Mixed Data Types*

---

## Description

This package provides a variety of nonparametric and semiparametric kernel methods that seamlessly handle a mix of continuous, unordered, and ordered factor data types (unordered and ordered factors are often referred to as ‘nominal’ and ‘ordinal’ categorical variables respectively). A vignette containing many of the examples found in the help files accompanying the **np** package that is intended to serve as a gentle introduction to this package can be accessed via `vignette("np", package="np")`.

For a listing of all routines in the **np** package type: `library(help="np")`.

Bandwidth selection is a key aspect of sound nonparametric and semiparametric kernel estimation. **np** is designed from the ground up to make bandwidth selection the focus of attention. To this end, one typically begins by creating a ‘bandwidth object’ which embodies all aspects of the method, including specific kernel functions, data names, data types, and the like. One then passes these bandwidth objects to other functions, and those functions can grab the specifics from the bandwidth object thereby removing potential inconsistencies and unnecessary repetition. Furthermore, many functions such as `plot` (which automatically calls `npplot`) can work with the bandwidth object directly without having to do the subsequent companion function evaluation.

As of **np** version 0.20-0, we allow the user to combine these steps. When using **np** versions 0.20-0 and higher, if the first step (bandwidth selection) is not performed explicitly then the second step will automatically call the omitted first step bandwidth selector using defaults unless otherwise specified, and the bandwidth object could then be retrieved retroactively if so desired via `objectname$bws`. Furthermore, options for bandwidth selection will be passed directly to the bandwidth selector function. Note that the combined approach would not be a wise choice for certain applications such as when bootstrapping (as it would involve unnecessary computation since the bandwidths would

properly be those for the original sample and not the bootstrap resamples) or when conducting quantile regression (as it would involve unnecessary computation when different quantiles are computed from the same conditional cumulative distribution estimate).

There are two ways in which you can interact with functions in np, either i) using data frames, or ii) using a formula interface, where appropriate.

To some, it may be natural to use the data frame interface. The R `data.frame` function preserves a variable's type once it has been cast (unlike `cbind`, which we avoid for this reason). If you find this most natural for your project, you first create a data frame casting data according to their type (i.e., one of continuous (default, `numeric`), `factor`, `ordered`). Then you would simply pass this data frame to the appropriate np function, for example `npudensbw(dat=data)`.

To others, however, it may be natural to use the formula interface that is used for the regression examples, among others. For nonparametric regression functions such as `npreg`, you would proceed as you would using `lm` (e.g., `bw <- npregbw(y~factor(x1)+x2)`) except that you would of course not need to specify, e.g., polynomials in variables, interaction terms, or create a number of dummy variables for a factor. Every function in np supports both interfaces, where appropriate.

Note that if your factor is in fact a character string such as, say, X being either "MALE" or "FEMALE", np will handle this directly, i.e., there is no need to map the string values into unique integers such as (0,1). Once the user casts a variable as a particular data type (i.e., `factor`, `ordered`, or continuous (default, `numeric`)), all subsequent methods automatically detect the type and use the appropriate kernel function and method where appropriate.

All estimation methods are fully multivariate, i.e., there are no limitations on the number of variables one can model (or number of observations for that matter). Execution time for most routines is, however, exponentially increasing in the number of observations and increases with the number of variables involved.

Nonparametric methods include unconditional density (distribution), conditional density (distribution), regression, mode, and quantile estimators along with gradients where appropriate, while semiparametric methods include single index, partially linear, and smooth (i.e., varying) coefficient models.

A number of tests are included such as consistent specification tests for parametric regression and quantile regression models along with tests of significance for nonparametric regression.

A variety of bootstrap methods for computing standard errors, nonparametric confidence bounds, and bias-corrected bounds are implemented.

A variety of bandwidth methods are implemented including fixed, nearest-neighbor, and adaptive nearest-neighbor.

A variety of data-driven methods of bandwidth selection are implemented, while the user can specify their own bandwidths should they so choose (either a raw bandwidth or scaling factor).

A flexible plotting utility, `npplot` (which is automatically invoked by `plot`), facilitates graphing of multivariate objects. An example for creating postscript graphs using the `npplot` utility and pulling this into a LaTeX document is provided.

The function `npksum` allows users to create or implement their own kernel estimators or tests should they so desire.

The underlying functions are written in C for computational efficiency. Despite this, due to their nature, data-driven bandwidth selection methods involving multivariate numerical search can be time-consuming, particularly for large datasets. A version of this package using the Rmpi wrapper

is under development that allows one to deploy this software in a clustered computing environment to facilitate computation involving large datasets.

To cite the np package, type `citation("np")` from within R for details.

## Details

The kernel methods in np employ the so-called ‘generalized product kernels’ found in Hall, Racine, and Li (2004), Li, Lin, and Racine (2013), Li, Ouyang, and Racine (2013), Li and Racine (2003), Li and Racine (2004), Li and Racine (2007), Li and Racine (2010), Ouyang, Li, and Racine (2006), and Racine and Li (2004), among others. For details on a particular method, kindly refer to the original references listed above.

We briefly describe the particulars of various univariate kernels used to generate the generalized product kernels that underlie the kernel estimators implemented in the np package. In a nutshell, the generalized kernel functions that underlie the kernel estimators in np are formed by taking the product of univariate kernels such as those listed below. When you cast your data as a particular type (continuous, factor, or ordered factor) in a data frame or formula, the routines will automatically recognize the type of variable being modelled and use the appropriate kernel type for each variable in the resulting estimator.

**Second Order Gaussian (*x* is continuous)**  $k(z) = \exp(-z^2/2)/\sqrt{2\pi}$  where  $z = (x_i - x)/h$ , and  $h > 0$ .

**Second Order Truncated Gaussian (*x* is continuous)**  $k(z) = (\exp(-z^2/2) - \exp(-b^2/2))/(\text{erf}(b/\sqrt{2})\sqrt{2\pi} - 2b\exp(-b^2/2))$  where  $z = (x_i - x)/h$ ,  $b > 0$ ,  $|z| \leq b$  and  $h > 0$ .

See `nptgauss` for details on modifying  $b$ .

**Second Order Epanechnikov (*x* is continuous)**  $k(z) = 3(1 - z^2/5)/(4\sqrt{5})$  if  $z^2 < 5$ , 0 otherwise, where  $z = (x_i - x)/h$ , and  $h > 0$ .

**Uniform (*x* is continuous)**  $k(z) = 1/2$  if  $|z| < 1$ , 0 otherwise, where  $z = (x_i - x)/h$ , and  $h > 0$ .

**Aitchison and Aitken (*x* is a (discrete) factor)**  $l(x_i, x, \lambda) = 1 - \lambda$  if  $x_i = x$ , and  $\lambda/(c - 1)$  if  $x_i \neq x$ , where  $c$  is the number of (discrete) outcomes assumed by the factor  $x$ .

Note that  $\lambda$  must lie between 0 and  $(c - 1)/c$ .

**Wang and van Ryzin (*x* is a (discrete) ordered factor)**  $l(x_i, x, \lambda) = 1 - \lambda$  if  $|x_i - x| = 0$ , and  $((1 - \lambda)/2)\lambda^{|x_i - x|}$  if  $|x_i - x| \geq 1$ .

Note that  $\lambda$  must lie between 0 and 1.

**Li and Racine (*x* is a (discrete) factor)**  $l(x_i, x, \lambda) = 1$  if  $x_i = x$ , and  $\lambda$  if  $x_i \neq x$ .

Note that  $\lambda$  must lie between 0 and 1.

**Li and Racine Normalised for Unconditional Objects (*x* is a (discrete) factor)**  $l(x_i, x, \lambda) = 1/(1 + (c - 1)\lambda)$  if  $x_i = x$ , and  $\lambda/(1 + (c - 1)\lambda)$  if  $x_i \neq x$ .

Note that  $\lambda$  must lie between 0 and 1.

**Li and Racine (*x* is a (discrete) ordered factor)**  $l(x_i, x, \lambda) = 1$  if  $|x_i - x| = 0$ , and  $\lambda^{|x_i - x|}$  if  $|x_i - x| \geq 1$ .

Note that  $\lambda$  must lie between 0 and 1.

**Li and Racine Normalised for Unconditional Objects (*x* is a (discrete) ordered factor)**  $l(x_i, x, \lambda) = (1 - \lambda)/(1 + \lambda)$  if  $|x_i - x| = 0$ , and  $(1 - \lambda)/(1 + \lambda)\lambda^{|x_i - x|}$  if  $|x_i - x| \geq 1$ .

Note that  $\lambda$  must lie between 0 and 1.

So, if you had two variables,  $x_{i1}$  and  $x_{i2}$ , and  $x_{i1}$  was continuous while  $x_{i2}$  was, say, binary (0/1), and you created a data frame of the form `X <- data.frame(x1,x2=factor(x2))`, then the kernel function used by np would be  $K(\cdot) = k(\cdot) \times l(\cdot)$  where the particular kernel functions  $k(\cdot)$  and  $l(\cdot)$  would be, say, the second order Gaussian (`ckertype="gaussian"`) and Aitchison and Aitken (`ukertype="aitchisonaitken"`) kernels by default, respectively (note that for conditional density and distribution objects we can specify kernels for the left-hand side and right-hand side variables in this manner using `cykertype="gaussian"`, `cxkertype="gaussian"` and `uykertype="aitchisonaitken"`, `uxkertype="aitchisonaitken"`).

Note that higher order continuous kernels (i.e., fourth, sixth, and eighth order) are derived from the second order kernels given above (see Li and Racine (2007) for details).

For particulars on any given method, kindly see the references listed for the method in question.

npcdens

---

*Kernel Conditional Density Estimation with Mixed Data Types*

---

## Description

npcdens computes kernel conditional density estimates on  $p + q$ -variate evaluation data, given a set of training data (both explanatory and dependent) and a bandwidth specification (a conbandwidth object or a bandwidth vector, bandwidth type, and kernel type) using the method of Hall, Racine, and Li (2004). The data may be continuous, discrete (unordered and ordered factors), or some combination thereof.

## Usage

```
npcdens(bws, ...)

## S3 method for class 'formula'
npcdens(bws, data = NULL, newdata = NULL, ...)

## S3 method for class 'call'
npcdens(bws, ...)

## S3 method for class 'conbandwidth'
npcdens(bws,
        txdat = stop("invoked without training data 'txdat'"),
        tydat = stop("invoked without training data 'tydat'"),
        exdat,
        eydat,
        gradients = FALSE,
        ...)

## Default S3 method:
npcdens(bws, txdat, tydat, ...)
```

## Arguments

bws	a bandwidth specification. This can be set as a conbandwidth object returned from a previous invocation of <a href="#">npcdensbw</a> , or as a $p + q$ -vector of bandwidths, with each element $i$ up to $i = q$ corresponding to the bandwidth for column $i$ in tydat, and each element $i$ from $i = q + 1$ to $i = p + q$ corresponding to the
-----	---

	bandwidth for column $i - q$ in <code>txdat</code> . If specified as a vector, then additional arguments will need to be supplied as necessary to specify the bandwidth type, kernel types, training data, and so on.
<code>gradients</code>	a logical value specifying whether to return estimates of the gradients at the evaluation points. Defaults to <code>FALSE</code> .
<code>...</code>	additional arguments supplied to specify the bandwidth type, kernel types, and so on. This is necessary if you specify <code>bws</code> as a $p+q$ -vector and not a <code>conbandwidth</code> object, and you do not desire the default behaviours. To do this, you may specify any of <code>bwmethod</code> , <code>bwscaling</code> , <code>bwtype</code> , <code>cxkertype</code> , <code>cxkerorder</code> , <code>cykertype</code> , <code>cykerorder</code> , <code>uxkertype</code> , <code>uykertype</code> , <code>oxkertype</code> , <code>oykertype</code> , as described in <a href="#">npcdensbw</a> .
<code>data</code>	an optional data frame, list or environment (or object coercible to a data frame by <a href="#">as.data.frame</a> ) containing the variables in the model. If not found in <code>data</code> , the variables are taken from <code>environment(bws)</code> , typically the environment from which <a href="#">npcdensbw</a> was called.
<code>newdata</code>	An optional data frame in which to look for evaluation data. If omitted, the training data are used.
<code>txdat</code>	a $p$ -variate data frame of sample realizations of explanatory data (training data). Defaults to the training data used to compute the bandwidth object.
<code>tydat</code>	a $q$ -variate data frame of sample realizations of dependent data (training data). Defaults to the training data used to compute the bandwidth object.
<code>exdat</code>	a $p$ -variate data frame of explanatory data on which conditional densities will be evaluated. By default, evaluation takes place on the data provided by <code>txdat</code> .
<code>eydat</code>	a $q$ -variate data frame of dependent data on which conditional densities will be evaluated. By default, evaluation takes place on the data provided by <code>tydat</code> .

## Details

`npcdens` implements a variety of methods for estimating multivariate conditional distributions ( $p + q$ -variate) defined over a set of possibly continuous and/or discrete (unordered, ordered) data. The approach is based on Li and Racine (2004) who employ ‘generalized product kernels’ that admit a mix of continuous and discrete data types.

Three classes of kernel estimators for the continuous data types are available: fixed, adaptive nearest-neighbor, and generalized nearest-neighbor. Adaptive nearest-neighbor bandwidths change with each sample realization in the set,  $x_i$ , when estimating the density at the point  $x$ . Generalized nearest-neighbor bandwidths change with the point at which the density is estimated,  $x$ . Fixed bandwidths are constant over the support of  $x$ .

Training and evaluation input data may be a mix of continuous (default), unordered discrete (to be specified in the data frames using [factor](#)), and ordered discrete (to be specified in the data frames using [ordered](#)). Data can be entered in an arbitrary order and data types will be detected automatically by the routine (see [np](#) for details).

A variety of kernels may be specified by the user. Kernels implemented for continuous data types include the second, fourth, sixth, and eighth order Gaussian and Epanechnikov kernels, and the uniform kernel. Unordered discrete data types use a variation on Aitchison and Aitken’s (1976) kernel, while ordered data types use a variation of the Wang and van Ryzin (1981) kernel.

**Value**

npcdens returns a `condensity` object. The generic accessor functions `fitted`, `se`, and `gradients`, extract estimated values, asymptotic standard errors on estimates, and gradients, respectively, from the returned object. Furthermore, the functions `predict`, `summary` and `plot` support objects of both classes. The returned objects have the following components:

<code>xbw</code>	bandwidth(s), scale factor(s) or nearest neighbours for the explanatory data, <code>txdat</code>
<code>ybw</code>	bandwidth(s), scale factor(s) or nearest neighbours for the dependent data, <code>tydat</code>
<code>xeval</code>	the evaluation points of the explanatory data
<code>yeval</code>	the evaluation points of the dependent data
<code>condens</code>	estimates of the conditional density at the evaluation points
<code>conderr</code>	standard errors of the conditional density estimates
<code>congrad</code>	if invoked with <code>gradients = TRUE</code> , estimates of the gradients at the evaluation points
<code>congerr</code>	if invoked with <code>gradients = TRUE</code> , standard errors of the gradients at the evaluation points
<code>log_likelihood</code>	log likelihood of the conditional density estimate

**Usage Issues**

If you are using data of mixed types, then it is advisable to use the `data.frame` function to construct your input data and not `cbind`, since `cbind` will typically not work as intended on mixed data types and will coerce the data to the same type.

```

### Arguments

formula	a symbolic description of variables on which bandwidth selection is to be performed. The details of constructing a formula are described below.
data	an optional data frame, list or environment (or object coercible to a data frame by <a href="#">as.data.frame</a> ) containing the variables in the model. If not found in data, the variables are taken from environment(formula), typically the environment from which the function is called.
subset	an optional vector specifying a subset of observations to be used in the fitting

	process.
na.action	a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of options, and is <code>na.fail</code> if that is unset. The (recommended) default is <code>na.omit</code> .
call	the original function call. This is passed internally by <code>np</code> when a bandwidth search has been implied by a call to another function. It is not recommended that the user set this.
xdat	a $p$ -variate data frame of explanatory data on which bandwidth selection will be performed. The data types may be continuous, discrete (unordered and ordered factors), or some combination thereof.
ydat	a $q$ -variate data frame of dependent data on which bandwidth selection will be performed. The data types may be continuous, discrete (unordered and ordered factors), or some combination thereof.
bws	a bandwidth specification. This can be set as a <code>conbandwidth</code> object returned from a previous invocation, or as a $p+q$ -vector of bandwidths, with each element $i$ up to $i = q$ corresponding to the bandwidth for column $i$ in <code>ydat</code> , and each element $i$ from $i = q + 1$ to $i = p + q$ corresponding to the bandwidth for column $i - q$ in <code>xdat</code> . In either case, the bandwidth supplied will serve as a starting point in the numerical search for optimal bandwidths. If specified as a vector, then additional arguments will need to be supplied as necessary to specify the bandwidth type, kernel types, selection methods, and so on. This can be left unset.
...	additional arguments supplied to specify the bandwidth type, kernel types, selection methods, and so on, detailed below.
bwmethod	which method to use to select bandwidths. <code>cv.ml</code> specifies likelihood cross-validation, <code>cv.ls</code> specifies least-squares cross-validation, and <code>normal-reference</code> just computes the ‘rule-of-thumb’ bandwidth $h_j$ using the standard formula $h_j = 1.06\sigma_j n^{-1/(2P+l)}$ , where $\sigma_j$ is an adaptive measure of spread of the $j$ th continuous variable defined as $\min(\text{standard deviation}, \text{mean absolute deviation}/1.4826, \text{interquartile range}/1.349)$ , $n$ the number of observations, $P$ the order of the kernel, and $l$ the number of continuous variables. Note that when there exist factors and the normal-reference rule is used, there is zero smoothing of the factors. Defaults to <code>cv.ml</code> .
bwscaling	a logical value that when set to <code>TRUE</code> the supplied bandwidths are interpreted as ‘scale factors’ ( $c_j$ ), otherwise when the value is <code>FALSE</code> they are interpreted as ‘raw bandwidths’ ( $h_j$ for continuous data types, $\lambda_j$ for discrete data types). For continuous data types, $c_j$ and $h_j$ are related by the formula $h_j = c_j \sigma_j n^{-1/(2P+l)}$ , where $\sigma_j$ is an adaptive measure of spread of continuous variable $j$ defined as $\min(\text{standard deviation}, \text{mean absolute deviation}/1.4826, \text{interquartile range}/1.349)$ , $n$ the number of observations, $P$ the order of the kernel, and $l$ the number of continuous variables. For discrete data types, $c_j$ and $h_j$ are related by the formula $h_j = c_j n^{-2/(2P+l)}$ , where here $j$ denotes discrete variable $j$ . Defaults to <code>FALSE</code> .
bwtype	character string used for the continuous variable bandwidth type, specifying the type of bandwidth to compute and return in the <code>conbandwidth</code> object. Defaults to <code>fixed</code> . Option summary: fixed: compute fixed bandwidths

	generalized_nn: compute generalized nearest neighbors
	adaptive_nn: compute adaptive nearest neighbors
bandwidth.compute	a logical value which specifies whether to do a numerical search for bandwidths or not. If set to FALSE, a conbandwidth object will be returned with bandwidths set to those specified in bws. Defaults to TRUE.
cxkertype	character string used to specify the continuous kernel type for xdat. Can be set as gaussian, epanechnikov, or uniform. Defaults to gaussian.
cxkerorder	numeric value specifying kernel order for xdat (one of (2,4,6,8)). Kernel order specified along with a uniform continuous kernel type will be ignored. Defaults to 2.
cykertype	character string used to specify the continuous kernel type for ydat. Can be set as gaussian, epanechnikov, or uniform. Defaults to gaussian.
cykerorder	numeric value specifying kernel order for ydat (one of (2,4,6,8)). Kernel order specified along with a uniform continuous kernel type will be ignored. Defaults to 2.
uxkertype	character string used to specify the unordered categorical kernel type. Can be set as aitchisonaitken or liracine. Defaults to aitchisonaitken.
uykertype	character string used to specify the unordered categorical kernel type. Can be set as aitchisonaitken or liracine.
oxkertype	character string used to specify the ordered categorical kernel type. Can be set as wangvanryzin or liracine. Defaults to liracine.
oykertype	character string used to specify the ordered categorical kernel type. Can be set as wangvanryzin or liracine.
nmulti	integer number of times to restart the process of finding extrema of the cross-validation function from different (random) initial points
remin	a logical value which when set as TRUE the search routine restarts from located minima for a minor gain in accuracy. Defaults to TRUE.
itmax	integer number of iterations before failure in the numerical optimization routine. Defaults to 10000.
ftol	fractional tolerance on the value of the cross-validation function evaluated at located minima (of order the machine precision or perhaps slightly larger so as not to be diddled by roundoff). Defaults to $1.490116e-07$ ( $1.0e+01*\sqrt{.Machine\$double.eps}$ ).
tol	tolerance on the position of located minima of the cross-validation function (tol should generally be no smaller than the square root of your machine's floating point precision). Defaults to $1.490116e-04$ ( $1.0e+04*\sqrt{.Machine\$double.eps}$ ).
small	a small number used to bracket a minimum (it is hopeless to ask for a bracketing interval of width less than $\sqrt{\epsilon}$ times its central value, a fractional width of only about $10^{-4}$ (single precision) or $3 \times 10^{-8}$ (double precision)). Defaults to $small = 1.490116e-05$ ( $1.0e+03*\sqrt{.Machine\$double.eps}$ ).
lbc.dir, dfc.dir, cfac.dir, initc.dir	lower bound, chi-square degrees of freedom, stretch factor, and initial non-random values for direction set search for Powell's algorithm for numeric variables. See Details

<code>lbd.dir, hbd.dir, dfac.dir, initd.dir</code>	lower bound, upper bound, stretch factor, and initial non-random values for direction set search for Powell's algorithm for categorical variables. See Details
<code>lbc.init, hbc.init, cfac.init</code>	lower bound, upper bound, and non-random initial values for scale factors for numeric variables for Powell's algorithm. See Details
<code>lbd.init, hbd.init, dfac.init</code>	lower bound, upper bound, and non-random initial values for scale factors for categorical variables for Powell's algorithm. See Details
<code>scale.init.categorical.sample</code>	a logical value that when set to TRUE scales <code>lbd.dir</code> , <code>hbd.dir</code> , <code>dfac.dir</code> , and <code>initd.dir</code> by $n^{-2/(2P+l)}$ , $n$ the number of observations, $P$ the order of the kernel, and $l$ the number of numeric variables. See Details
<code>memfac</code>	The algorithm to compute the least-squares objective function uses a block-based algorithm to eliminate or minimize redundant kernel evaluations. Due to memory, hardware and software constraints, a maximum block size must be imposed by the algorithm. This block size is roughly equal to <code>memfac*10^5</code> elements. Empirical tests on modern hardware find that a <code>memfac</code> of 500 performs well. If you experience out of memory errors, or strange behaviour for large data sets (>100k elements) setting <code>memfac</code> to a lower value may fix the problem.

## Details

`npcdensbw` implements a variety of methods for choosing bandwidths for multivariate distributions ( $p + q$ -variate) defined over a set of possibly continuous and/or discrete (unordered, ordered) data. The approach is based on Li and Racine (2004) who employ 'generalized product kernels' that admit a mix of continuous and discrete data types.

The cross-validation methods employ multivariate numerical search algorithms (direction set (Powell's) methods in multidimensions).

Bandwidths can (and will) differ for each variable which is, of course, desirable.

Three classes of kernel estimators for the continuous data types are available: fixed, adaptive nearest-neighbor, and generalized nearest-neighbor. Adaptive nearest-neighbor bandwidths change with each sample realization in the set,  $x_i$ , when estimating the density at the point  $x$ . Generalized nearest-neighbor bandwidths change with the point at which the density is estimated,  $x$ . Fixed bandwidths are constant over the support of  $x$ .

`npcdensbw` may be invoked *either* with a formula-like symbolic description of variables on which bandwidth selection is to be performed *or* through a simpler interface whereby data is passed directly to the function via the `xdat` and `ydat` parameters. Use of these two interfaces is **mutually exclusive**.

Data contained in the data frames `xdat` and `ydat` may be a mix of continuous (default), unordered discrete (to be specified in the data frames using `factor`), and ordered discrete (to be specified in the data frames using `ordered`). Data can be entered in an arbitrary order and data types will be detected automatically by the routine (see [np](#) for details).

Data for which bandwidths are to be estimated may be specified symbolically. A typical description has the form dependent data ~ explanatory data, where dependent data and explanatory

data are both series of variables specified by name, separated by the separation character '+'. For example,  $y_1 + y_2 \sim x_1 + x_2$  specifies that the bandwidths for the joint distribution of variables  $y_1$  and  $y_2$  conditioned on  $x_1$  and  $x_2$  are to be estimated. See below for further examples.

A variety of kernels may be specified by the user. Kernels implemented for continuous data types include the second, fourth, sixth, and eighth order Gaussian and Epanechnikov kernels, and the uniform kernel. Unordered discrete data types use a variation on Aitchison and Aitken's (1976) kernel, while ordered data types use a variation of the Wang and van Ryzin (1981) kernel.

The optimizer invoked for search is Powell's conjugate direction method which requires the setting of (non-random) initial values and search directions for bandwidths, and, when restarting, random values for successive invocations. Bandwidths for numeric variables are scaled by robust measures of spread, the sample size, and the number of numeric variables where appropriate. Two sets of parameters for bandwidths for numeric can be modified, those for initial values for the parameters themselves, and those for the directions taken (Powell's algorithm does not involve explicit computation of the function's gradient). The default values are set by considering search performance for a variety of difficult test cases and simulated cases. We highly recommend restarting search a large number of times to avoid the presence of local minima (achieved by modifying `nmulti`). Further refinement for difficult cases can be achieved by modifying these sets of parameters. However, these parameters are intended more for the authors of the package to enable 'tuning' for various methods rather than for the user themselves.

## Value

`npcdensbw` returns a `conbandwidth` object, with the following components:

<code>xbw</code>	bandwidth(s), scale factor(s) or nearest neighbours for the explanatory data, <code>xdat</code>
<code>ybw</code>	bandwidth(s), scale factor(s) or nearest neighbours for the dependent data, <code>ydat</code>
<code>fval</code>	objective function value at minimum

if `bwtype` is set to `fixed`, an object containing bandwidths (or scale factors if `bwscaling = TRUE`) is returned. If it is set to `generalized_nn` or `adaptive_nn`, then instead the  $k$ th nearest neighbors are returned for the continuous variables while the discrete kernel bandwidths are returned for the discrete variables.

The functions `predict`, `summary` and `plot` support objects of type `conbandwidth`.

## Usage Issues

If you are using data of mixed types, then it is advisable to use the `data.frame` function to construct your input data and not `cbind`, since `cbind` will typically not work as intended on mixed data types and will coerce the data to the same type.

Caution: multivariate data-driven bandwidth selection methods are, by their nature, *computationally intensive*. Virtually all methods require dropping the  $i$ th observation from the data set, computing an object, repeating this for all observations in the sample, then averaging each of these leave-one-out estimates for a *given* value of the bandwidth vector, and only then repeating this a large number of times in order to conduct multivariate numerical minimization/maximization. Furthermore, due to the potential for local minima/maxima, *restarting this procedure a large number of times may often be necessary*. This can be frustrating for users possessing large datasets. For exploratory

purposes, you may wish to override the default search tolerances, say, setting `ftol=.01` and `tol=.01` and conduct multistarting (the default is to restart `min(5, ncol(xdat,ydat))` times) as is done for a number of examples. Once the procedure terminates, you can restart search with default tolerances using those bandwidths obtained from the less rigorous search (i.e., set `bws=bw` on subsequent calls to this routine where `bw` is the initial bandwidth object). A version of this package using the Rmpi wrapper is under development that allows one to deploy this software in a clustered computing environment to facilitate computation involving large datasets.

npcdist

---

*Kernel Conditional Distribution Estimation with Mixed Data Types*

---

## Description

npcdist computes kernel cumulative conditional distribution estimates on  $p + q$ -variate evaluation data, given a set of training data (both explanatory and dependent) and a bandwidth specification (a condbandwidth object or a bandwidth vector, bandwidth type, and kernel type) using the method of Li and Racine (2008) and Li, Lin, and Racine (2013). The data may be continuous, discrete (unordered and ordered factors), or some combination thereof.

## Usage

```

npcdist(bws, ...)

## S3 method for class 'formula'
npcdist(bws, data = NULL, newdata = NULL, ...)

```

```
## S3 method for class 'call'
npcdist(bws, ...)

## S3 method for class 'condbandwidth'
npcdist(bws,
        txdat = stop("invoked without training data 'txdat'"),
        tydat = stop("invoked without training data 'tydat'"),
        exdat,
        eydat,
        gradients = FALSE,
        ...)

## Default S3 method:
npcdist(bws, txdat, tydat, ...)
```

## Arguments

bws	a bandwidth specification. This can be set as a <code>condbandwidth</code> object returned from a previous invocation of <code>npcdistbw</code> , or as a $p + q$ -vector of bandwidths, with each element $i$ up to $i = q$ corresponding to the bandwidth for column $i$ in <code>tydat</code> , and each element $i$ from $i = q + 1$ to $i = p + q$ corresponding to the bandwidth for column $i - q$ in <code>txdat</code> . If specified as a vector, then additional arguments will need to be supplied as necessary to specify the bandwidth type, kernel types, training data, and so on.
gradients	a logical value specifying whether to return estimates of the gradients at the evaluation points. Defaults to <code>FALSE</code> .
...	additional arguments supplied to specify the bandwidth type, kernel types, and so on. This is necessary if you specify <code>bws</code> as a $p+q$ -vector and not a <code>condbandwidth</code> object, and you do not desire the default behaviours. To do this, you may specify any of <code>bwmethod</code> , <code>bwscaling</code> , <code>bwtype</code> , <code>cxkertype</code> , <code>cxkerorder</code> , <code>cykertype</code> , <code>cykerorder</code> , <code>uxkertype</code> , <code>oxkertype</code> , <code>oykertype</code> , as described in <code>npcdistbw</code> .
data	an optional data frame, list or environment (or object coercible to a data frame by <code>as.data.frame</code> ) containing the variables in the model. If not found in <code>data</code> , the variables are taken from <code>environment(bws)</code> , typically the environment from which <code>npcdistbw</code> was called.
newdata	An optional data frame in which to look for evaluation data. If omitted, the training data are used.
txdat	a $p$ -variate data frame of sample realizations of explanatory data (training data). Defaults to the training data used to compute the bandwidth object.
tydat	a $q$ -variate data frame of sample realizations of dependent data (training data). Defaults to the training data used to compute the bandwidth object.
exdat	a $p$ -variate data frame of explanatory data on which cumulative conditional distributions will be evaluated. By default, evaluation takes place on the data provided by <code>txdat</code> .

**eydat** a  $q$ -variate data frame of dependent data on which cumulative conditional distributions will be evaluated. By default, evaluation takes place on the data provided by **tydat**.

## Details

`npcdist` implements a variety of methods for estimating multivariate conditional cumulative distributions ( $p+q$ -variate) defined over a set of possibly continuous and/or discrete (unordered, ordered) data. The approach is based on Li and Racine (2004) who employ ‘generalized product kernels’ that admit a mix of continuous and discrete data types.

Three classes of kernel estimators for the continuous data types are available: fixed, adaptive nearest-neighbor, and generalized nearest-neighbor. Adaptive nearest-neighbor bandwidths change with each sample realization in the set,  $x_i$ , when estimating the cumulative conditional distribution at the point  $x$ . Generalized nearest-neighbor bandwidths change with the point at which the cumulative conditional distribution is estimated,  $x$ . Fixed bandwidths are constant over the support of  $x$ .

Training and evaluation input data may be a mix of continuous (default), unordered discrete (to be specified in the data frames using `factor`), and ordered discrete (to be specified in the data frames using `ordered`). Data can be entered in an arbitrary order and data types will be detected automatically by the routine (see `np` for details).

A variety of kernels may be specified by the user. Kernels implemented for continuous data types include the second, fourth, sixth, and eighth order Gaussian and Epanechnikov kernels, and the uniform kernel. Unordered discrete data types use a variation on Aitchison and Aitken’s (1976) kernel, while ordered data types use a variation of the Wang and van Ryzin (1981) kernel.

## Value

`npcdist` returns a `condistribution` object. The generic accessor functions `fitted`, `se`, and `gradients`, extract estimated values, asymptotic standard errors on estimates, and gradients, respectively, from the returned object. Furthermore, the functions `predict`, `summary` and `plot` support objects of both classes. The returned objects have the following components:

<b>xbw</b>	bandwidth(s), scale factor(s) or nearest neighbours for the explanatory data, <code>txdat</code>
<b>ybw</b>	bandwidth(s), scale factor(s) or nearest neighbours for the dependent data, <code>tydat</code>
<b>xeval</b>	the evaluation points of the explanatory data
<b>yeval</b>	the evaluation points of the dependent data
<b>condist</b>	estimates of the conditional cumulative distribution at the evaluation points
<b>conderr</b>	standard errors of the cumulative conditional distribution estimates
<b>congrad</b>	if invoked with <code>gradients = TRUE</code> , estimates of the gradients at the evaluation points
<b>congerr</b>	if invoked with <code>gradients = TRUE</code> , standard errors of the gradients at the evaluation points
<b>log_likelihood</b>	log likelihood of the cumulative conditional distribution estimate

## Usage Issues

If you are using data of mixed types, then it is advisable to use the `data.frame` function to construct your input data and not `cbind`, since `cbind` will typically not work as intended on mixed data types and will coerce the data to the same type.

## Arguments

formula	a symbolic description of variables on which bandwidth selection is to be performed. The details of constructing a formula are described below.
data	an optional data frame, list or environment (or object coercible to a data frame by <code>as.data.frame</code> ) containing the variables in the model. If not found in data, the variables are taken from <code>environment(formula)</code> , typically the environment from which the function is called.
subset	an optional vector specifying a subset of observations to be used in the fitting process.
na.action	a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of options, and is <code>na.fail</code> if that is unset. The (recommended) default is <code>na.omit</code> .
call	the original function call. This is passed internally by <code>np</code> when a bandwidth search has been implied by a call to another function. It is not recommended that the user set this.
gdata	a grid of data on which the indicator function for least-squares cross-validation is to be computed (can be the sample or a grid of quantiles).
xdat	a $p$ -variate data frame of explanatory data on which bandwidth selection will be performed. The data types may be continuous, discrete (unordered and ordered factors), or some combination thereof.
ydat	a $q$ -variate data frame of dependent data on which bandwidth selection will be performed. The data types may be continuous, discrete (ordered factors), or some combination thereof.
gydat	a grid of data on which the indicator function for least-squares cross-validation is to be computed (can be the sample or a grid of quantiles for ydat).
bws	a bandwidth specification. This can be set as a <code>condbandwidth</code> object returned from a previous invocation, or as a $p+q$ -vector of bandwidths, with each element $i$ up to $i = q$ corresponding to the bandwidth for column $i$ in ydat, and each element $i$ from $i = q + 1$ to $i = p + q$ corresponding to the bandwidth for column $i - q$ in xdat. In either case, the bandwidth supplied will serve as a starting point in the numerical search for optimal bandwidths. If specified as a vector, then additional arguments will need to be supplied as necessary to specify the bandwidth type, kernel types, selection methods, and so on. This can be left unset.
...	additional arguments supplied to specify the bandwidth type, kernel types, selection methods, and so on, detailed below.

bwmethod	which method to use to select bandwidths. <code>cv.ls</code> specifies least-squares cross-validation (Li, Lin and Racine (2013)), and <code>normal-reference</code> just computes the ‘rule-of-thumb’ bandwidth $h_j$ using the standard formula $h_j = 1.06\sigma_j n^{-1/(2P+l)}$ , where $\sigma_j$ is an adaptive measure of spread of the $j$ th continuous variable defined as $\min(\text{standard deviation}, \text{mean absolute deviation}/1.4826, \text{interquartile range}/1.349)$ , $n$ the number of observations, $P$ the order of the kernel, and $l$ the number of continuous variables. Note that when there exist factors and the normal-reference rule is used, there is zero smoothing of the factors. Defaults to <code>cv.ls</code> .
bwscaling	a logical value that when set to <code>TRUE</code> the supplied bandwidths are interpreted as ‘scale factors’ ( $c_j$ ), otherwise when the value is <code>FALSE</code> they are interpreted as ‘raw bandwidths’ ( $h_j$ for continuous data types, $\lambda_j$ for discrete data types). For continuous data types, $c_j$ and $h_j$ are related by the formula $h_j = c_j\sigma_j n^{-1/(2P+l)}$ , where $\sigma_j$ is an adaptive measure of spread of continuous variable $j$ defined as $\min(\text{standard deviation}, \text{mean absolute deviation}/1.4826, \text{interquartile range}/1.349)$ , $n$ the number of observations, $P$ the order of the kernel, and $l$ the number of continuous variables. For discrete data types, $c_j$ and $h_j$ are related by the formula $h_j = c_j n^{-2/(2P+l)}$ , where here $j$ denotes discrete variable $j$ . Defaults to <code>FALSE</code> .
bwtype	character string used for the continuous variable bandwidth type, specifying the type of bandwidth to compute and return in the <code>condbandwidth</code> object. Defaults to <code>fixed</code> . Option summary: <code>fixed</code> : compute fixed bandwidths <code>generalized_nn</code> : compute generalized nearest neighbors <code>adaptive_nn</code> : compute adaptive nearest neighbors
bandwidth.compute	a logical value which specifies whether to do a numerical search for bandwidths or not. If set to <code>FALSE</code> , a <code>condbandwidth</code> object will be returned with bandwidths set to those specified in <code>bws</code> . Defaults to <code>TRUE</code> .
cxkertype	character string used to specify the continuous kernel type for <code>xdat</code> . Can be set as <code>gaussian</code> , <code>epanechnikov</code> , or <code>uniform</code> . Defaults to <code>gaussian</code> .
cxkerorder	numeric value specifying kernel order for <code>xdat</code> (one of (2,4,6,8)). Kernel order specified along with a uniform continuous kernel type will be ignored. Defaults to 2.
cykertype	character string used to specify the continuous kernel type for <code>ydat</code> . Can be set as <code>gaussian</code> , <code>epanechnikov</code> , or <code>uniform</code> . Defaults to <code>gaussian</code> .
cykerorder	numeric value specifying kernel order for <code>ydat</code> (one of (2,4,6,8)). Kernel order specified along with a uniform continuous kernel type will be ignored. Defaults to 2.
uxkertype	character string used to specify the unordered categorical kernel type. Can be set as <code>aitchisonaitken</code> or <code>liracine</code> . Defaults to <code>aitchisonaitken</code> .
oxkertype	character string used to specify the ordered categorical kernel type. Can be set as <code>wangvanryzin</code> or <code>liracine</code> . Defaults to <code>liracine</code> .
oykertype	character string used to specify the ordered categorical kernel type. Can be set as <code>wangvanryzin</code> or <code>liracine</code> .
nmulti	integer number of times to restart the process of finding extrema of the cross-validation function from different (random) initial points

remin	a logical value which when set as TRUE the search routine restarts from located minima for a minor gain in accuracy. Defaults to TRUE.
itmax	integer number of iterations before failure in the numerical optimization routine. Defaults to 10000.
do.full.integral	a logical value which when set as TRUE evaluates the moment-based integral on the entire sample.
ngrid	integer number of grid points to use when computing the moment-based integral. Defaults to 100.
ftol	fractional tolerance on the value of the cross-validation function evaluated at located minima (of order the machine precision or perhaps slightly larger so as not to be diddled by roundoff). Defaults to $1.490116e-07$ ( $1.0e+01*\sqrt{.Machine\$double.eps}$ ).
tol	tolerance on the position of located minima of the cross-validation function (tol should generally be no smaller than the square root of your machine's floating point precision). Defaults to $1.490116e-04$ ( $1.0e+04*\sqrt{.Machine\$double.eps}$ ).
small	a small number used to bracket a minimum (it is hopeless to ask for a bracketing interval of width less than $\sqrt{\epsilon}$ times its central value, a fractional width of only about $10^{-4}$ (single precision) or $3 \times 10^{-8}$ (double precision)). Defaults to $1.490116e-05$ ( $1.0e+03*\sqrt{.Machine\$double.eps}$ ).
lbc.dir, dfc.dir, cfac.dir, initc.dir	lower bound, chi-square degrees of freedom, stretch factor, and initial non-random values for direction set search for Powell's algorithm for numeric variables. See Details
lbd.dir, hbd.dir, dfac.dir, initd.dir	lower bound, upper bound, stretch factor, and initial non-random values for direction set search for Powell's algorithm for categorical variables. See Details
lbc.init, hbc.init, cfac.init	lower bound, upper bound, and non-random initial values for scale factors for numeric variables for Powell's algorithm. See Details
lbd.init, hbd.init, dfac.init	lower bound, upper bound, and non-random initial values for scale factors for categorical variables for Powell's algorithm. See Details
scale.init.categorical.sample	a logical value that when set to TRUE scales lbd.dir, hbd.dir, dfac.dir, and initd.dir by $n^{-2/(2P+l)}$ , $n$ the number of observations, $P$ the order of the kernel, and $l$ the number of numeric variables. See Details
memfac	The algorithm to compute the least-squares objective function uses a block-based algorithm to eliminate or minimize redundant kernel evaluations. Due to memory, hardware and software constraints, a maximum block size must be imposed by the algorithm. This block size is roughly equal to $\text{memfac} \times 10^5$ elements. Empirical tests on modern hardware find that a memfac of around 500 performs well. If you experience out of memory errors, or strange behaviour for large data sets (>100k elements) setting memfac to a lower value may fix the problem.

## Details

npcdistbw implements a variety of methods for choosing bandwidths for multivariate distributions ( $p + q$ -variate) defined over a set of possibly continuous and/or discrete (unordered `xdat`, ordered `xdat` and `ydat`) data. The approach is based on Li and Racine (2004) who employ ‘generalized product kernels’ that admit a mix of continuous and discrete data types.

The cross-validation methods employ multivariate numerical search algorithms (direction set (Powell’s) methods in multidimensions).

Bandwidths can (and will) differ for each variable which is, of course, desirable.

Three classes of kernel estimators for the continuous data types are available: fixed, adaptive nearest-neighbor, and generalized nearest-neighbor. Adaptive nearest-neighbor bandwidths change with each sample realization in the set,  $x_i$ , when estimating the cumulative distribution at the point  $x$ . Generalized nearest-neighbor bandwidths change with the point at which the cumulative distribution is estimated,  $x$ . Fixed bandwidths are constant over the support of  $x$ .

npcdistbw may be invoked *either* with a formula-like symbolic description of variables on which bandwidth selection is to be performed *or* through a simpler interface whereby data is passed directly to the function via the `xdat` and `ydat` parameters. Use of these two interfaces is **mutually exclusive**.

Data contained in the data frame `xdat` may be a mix of continuous (default), unordered discrete (to be specified in the data frames using `factor`), and ordered discrete (to be specified in the data frames using `ordered`). Data contained in the data frame `ydat` may be a mix of continuous (default) and ordered discrete (to be specified in the data frames using `ordered`). Data can be entered in an arbitrary order and data types will be detected automatically by the routine (see `np` for details).

Data for which bandwidths are to be estimated may be specified symbolically. A typical description has the form dependent data ~ explanatory data, where dependent data and explanatory data are both series of variables specified by name, separated by the separation character ‘+’. For example, `y1 + y2 ~ x1 + x2` specifies that the bandwidths for the joint distribution of variables `y1` and `y2` conditioned on `x1` and `x2` are to be estimated. See below for further examples.

A variety of kernels may be specified by the user. Kernels implemented for continuous data types include the second, fourth, sixth, and eighth order Gaussian and Epanechnikov kernels, and the uniform kernel. Unordered discrete data types use a variation on Aitchison and Aitken’s (1976) kernel, while ordered data types use a variation of the Wang and van Ryzin (1981) kernel.

The optimizer invoked for search is Powell’s conjugate direction method which requires the setting of (non-random) initial values and search directions for bandwidths, and, when restarting, random values for successive invocations. Bandwidths for numeric variables are scaled by robust measures of spread, the sample size, and the number of numeric variables where appropriate. Two sets of parameters for bandwidths for numeric can be modified, those for initial values for the parameters themselves, and those for the directions taken (Powell’s algorithm does not involve explicit computation of the function’s gradient). The default values are set by considering search performance for a variety of difficult test cases and simulated cases. We highly recommend restarting search a large number of times to avoid the presence of local minima (achieved by modifying `nmulti`). Further refinement for difficult cases can be achieved by modifying these sets of parameters. However, these parameters are intended more for the authors of the package to enable ‘tuning’ for various methods rather than for the user themselves.

**Value**

npcdistbw returns a `condbandwidth` object, with the following components:

<code>xbw</code>	bandwidth(s), scale factor(s) or nearest neighbours for the explanatory data, <code>xdat</code>
<code>ybw</code>	bandwidth(s), scale factor(s) or nearest neighbours for the dependent data, <code>ydat</code>
<code>fval</code>	objective function value at minimum

if `bwtype` is set to `fixed`, an object containing bandwidths (or scale factors if `bwscaling = TRUE`) is returned. If it is set to `generalized_nn` or `adaptive_nn`, then instead the  $k$ th nearest neighbors are returned for the continuous variables while the discrete kernel bandwidths are returned for the discrete variables.

The functions `predict`, `summary` and `plot` support objects of type `condbandwidth`.

**Usage Issues**

If you are using data of mixed types, then it is advisable to use the `data.frame` function to construct your input data and not `cbind`, since `cbind` will typically not work as intended on mixed data types and will coerce the data to the same type.

Caution: multivariate data-driven bandwidth selection methods are, by their nature, *computationally intensive*. Virtually all methods require dropping the  $i$ th observation from the data set, computing an object, repeating this for all observations in the sample, then averaging each of these leave-one-out estimates for a *given* value of the bandwidth vector, and only then repeating this a large number of times in order to conduct multivariate numerical minimization/maximization. Furthermore, due to the potential for local minima/maxima, *restarting this procedure a large number of times may often be necessary*. This can be frustrating for users possessing large datasets. For exploratory purposes, you may wish to override the default search tolerances, say, setting `ftol=.01` and `tol=.01` and conduct multistarting (the default is to restart `min(5, ncol(xdat,ydat))` times) as is done for a number of examples. Once the procedure terminates, you can restart search with default tolerances using those bandwidths obtained from the less rigorous search (i.e., set `bws=bw` on subsequent calls to this routine where `bw` is the initial bandwidth object). A version of this package using the `Rmpi` wrapper is under development that allows one to deploy this software in a clustered computing environment to facilitate computation involving large datasets.

npcmstest

*Kernel Consistent Model Specification Test with Mixed Data Types*

## Description

npcmstest implements a consistent test for correct specification of parametric regression models (linear or nonlinear) as described in Hsiao, Li, and Racine (2007).

## Usage

```
npcmstest(formula,
          data = NULL,
          subset,
          xdat,
          ydat,
          model = stop(paste(sQuote("model"), " has not been provided")),
          distribution = c("bootstrap", "asymptotic"),
          boot.method = c("iid", "wild", "wild-rademacher"),
          boot.num = 399,
          pivot = TRUE,
          density.weighted = TRUE,
          random.seed = 42,
          ...)
```

## Arguments

formula	a symbolic description of variables on which the test is to be performed. The details of constructing a formula are described below.
data	an optional data frame, list or environment (or object coercible to a data frame by <a href="#">as.data.frame</a> ) containing the variables in the model. If not found in data, the variables are taken from environment(formula), typically the environment from which the function is called.
subset	an optional vector specifying a subset of observations to be used.

model	a model object obtained from a call to <a href="#">lm</a> (or <a href="#">glm</a> ). Important: the call to either <a href="#">glm</a> or <a href="#">lm</a> must have the arguments <code>x=TRUE</code> and <code>y=TRUE</code> or <code>npcmstest</code> will not work. Also, the test is based on residual bootstrapping hence the outcome must be continuous (which rules out Logit, Probit, and Count models).
xdat	a $p$ -variate data frame of explanatory data (training data) used to calculate the regression estimators.
ydat	a one (1) dimensional numeric or integer vector of dependent data, each element $i$ corresponding to each observation (row) $i$ of <code>xdat</code> .
distribution	a character string used to specify the method of estimating the distribution of the statistic to be calculated. <code>bootstrap</code> will conduct bootstrapping. <code>asymptotic</code> will use the normal distribution. Defaults to <code>bootstrap</code> .
boot.method	a character string used to specify the bootstrap method. <code>iid</code> will generate independent identically distributed draws. <code>wild</code> will use a wild bootstrap. <code>wild-rademacher</code> will use a wild bootstrap with Rademacher variables. Defaults to <code>iid</code> .
boot.num	an integer value specifying the number of bootstrap replications to use. Defaults to 399.
pivot	a logical value specifying whether the statistic should be normalised such that it approaches $N(0, 1)$ in distribution. Defaults to <code>TRUE</code> .
density.weighted	a logical value specifying whether the statistic should be weighted by the density of <code>xdat</code> . Defaults to <code>TRUE</code> .
random.seed	an integer used to seed R's random number generator. This is to ensure replicability. Defaults to 42.
...	additional arguments supplied to control bandwidth selection on the residuals. One can specify the bandwidth type, kernel types, and so on. To do this, you may specify any of <code>bwscaling</code> , <code>bwtype</code> , <code>ckertype</code> , <code>ckerorder</code> , <code>ukertype</code> , <code>okertype</code> , as described in <a href="#">npregbw</a> . This is necessary if you specify <code>bws</code> as a $p$ -vector and not a bandwidth object, and you do not desire the default behaviours.

## Value

`npcmstest` returns an object of type `cmstest` with the following components, components will contain information related to  $J_n$  or  $I_n$  depending on the value of `pivot`:

$J_n$	the statistic $J_n$
$I_n$	the statistic $I_n$
<code>Omega.hat</code>	as described in Hsiao, C. and Q. Li and J.S. Racine.
<code>q.*</code>	the various quantiles of the statistic $J_n$ (or $I_n$ if <code>pivot=FALSE</code> ) are in components <code>q.90</code> , <code>q.95</code> , <code>q.99</code> (one-sided 1%, 5%, 10% critical values)
<code>P</code>	the P-value of the statistic
<code>Jn.bootstrap</code>	if <code>pivot=TRUE</code> contains the bootstrap replications of $J_n$
<code>In.bootstrap</code>	if <code>pivot=FALSE</code> contains the bootstrap replications of $I_n$

[summary](#) supports object of type `cmstest`.

## Usage Issues

npcmstest supports regression objects generated by `lm` and uses features specific to objects of type `lm` hence if you attempt to pass objects of a different type the function cannot be expected to work.

If you are using data of mixed types, then it is advisable to use the `data.frame` function to construct your input data and not `cbind`, since `cbind` will typically not work as intended on mixed data types and will coerce the data to the same type.

npcmstest(model = model, xdat = X, ydat = growth)

detach(oecdpanel)

## End(Not run)

```

npconmode

*Kernel Modal Regression with Mixed Data Types*

## Description

npconmode performs kernel modal regression on mixed data, and finds the conditional mode given a set of training data, consisting of explanatory data and dependent data, and possibly evaluation data. Automatically computes various in sample and out of sample measures of accuracy.

## Usage

```

npconmode(bws, ...)

## S3 method for class 'formula'
npconmode(bws, data = NULL, newdata = NULL, ...)

## S3 method for class 'call'
npconmode(bws, ...)

## Default S3 method:
npconmode(bws, txdat, tydat, ...)

## S3 method for class 'conbandwidth'
npconmode(bws,
          txdat = stop("invoked without training data 'txdat'"),
          tydat = stop("invoked without training data 'tydat'"),
          exdat,
          eydat,
          ...)

```

## Arguments

bws	a bandwidth specification. This can be set as a conbandwidth object returned from an invocation of <a href="#">npcdensbw</a>
...	additional arguments supplied to specify the bandwidth type, kernel types, and so on, detailed below. This is necessary if you specify bws as a $p + q$ -vector and not a conbandwidth object, and you do not desire the default behaviours.

data	an optional data frame, list or environment (or object coercible to a data frame by <a href="#">as.data.frame</a> ) containing the variables in the model. If not found in data, the variables are taken from <code>environment(bws)</code> , typically the environment from which <a href="#">npcdensbw</a> was called.
newdata	An optional data frame in which to look for evaluation data. If omitted, the training data are used.
txdat	a $p$ -variate data frame of explanatory data (conditioning data) used to calculate the regression estimators. Defaults to the training data used to compute the bandwidth object.
tydat	a one (1) dimensional vector of unordered or ordered factors, containing the dependent data. Defaults to the training data used to compute the bandwidth object.
exdat	a $p$ -variate data frame of points on which the regression will be estimated (evaluation data). By default, evaluation takes place on the data provided by <code>txdat</code> .
eydat	a one (1) dimensional numeric or integer vector of the true values (outcomes) of the dependent variable. By default, evaluation takes place on the data provided by <code>tydat</code> .

## Value

`npconmode` returns a `conmode` object with the following components:

<code>conmode</code>	a vector of type factor (or ordered factor) containing the conditional mode at each evaluation point
<code>condens</code>	a vector of numeric type containing the modal density estimates at each evaluation point
<code>xeval</code>	a data frame of evaluation points
<code>yeval</code>	a vector of type factor (or ordered factor) containing the actual outcomes, or NA if not provided
<code>confusion.matrix</code>	the confusion matrix or NA if outcomes are not available
<code>CCR.overall</code>	the overall correct classification ratio, or NA if outcomes are not available
<code>CCR.byoutcome</code>	a numeric vector containing the correct classification ratio by outcome, or NA if outcomes are not available
<code>fit.mcfadden</code>	the McFadden-Puig-Kerschner performance measure or NA if outcomes are not available

The functions [mode](#), and [fitted](#) may be used to extract the conditional mode estimates, and the conditional density estimates at the conditional mode, respectively, from the resulting object. Also, [summary](#) supports `conmode` objects.

## Usage Issues

If you are using data of mixed types, then it is advisable to use the [data.frame](#) function to construct your input data and not [cbind](#), since [cbind](#) will typically not work as intended on mixed data types and will coerce the data to the same type.

npcopula

*Kernel Copula Estimation with Mixed Data Types*

## Description

npcopula implements the nonparametric mixed data kernel copula approach of Racine (2015) for an arbitrary number of dimensions

## Usage

```
npcopula(bws,
         data,
         u = NULL,
         n.quasi.inv = 1000,
         er.quasi.inv = 1)
```

## Arguments

bws	an unconditional joint distribution (npudistbw) or joint density (npudensbw) bandwidth object (if bws is delivered via npudistbw the copula distribution is estimated, while if bws is delivered via npudensbw the copula density is estimated)
data	a data frame containing variables used to construct bws
u	an optional matrix of real numbers lying in [0,1], each column of which corresponds to the vector of uth quantile values desired for each variable in the copula (otherwise the u values returned are those corresponding to the sample realizations)
n.quasi.inv	number of grid points generated when u is provided in order to compute the quasi-inverse of each marginal distribution (see details)
er.quasi.inv	number passed to <a href="#">extendrange</a> when u is provided specifying the fraction by which the data range should be extended when constructing the grid used to compute the quasi-inverse (see details)

## Details

npcopula computes the nonparametric copula or copula density using inversion (Nelsen (2006), page 51). For the inversion approach, we exploit Sklar's theorem (Corollary 2.3.7, Nelsen (2006)) to produce copulas directly from the joint distribution function using  $C(u, v) = H(F^{-1}(u), G^{-1}(v))$  rather than the typical approach that instead uses  $H(x, y) = C(F(x), G(y))$ . Whereas the latter requires kernel density estimation on a d-dimensional unit hypercube which necessitates the use of boundary correction methods, the former does not.

Note that if u is provided then [expand.grid](#) is called on u. As the dimension increases this can become unwieldy and potentially consume an enormous amount of memory unless the number of grid points is kept very small. Given that computing the copula on a grid is typically done for

graphical purposes, providing  $u$  is typically done for two-dimensional problems only. Even here, however, providing a grid of length 100 will expand into a matrix of dimension 10000 by 2 which, though not memory intensive, may be computationally burdensome.

The ‘quasi-inverse’ is computed via Definition 2.3.6 from Nelsen (2006). We compute an equi-quantile grid on the range of the data of length  $n.quasi.inv/2$ . We then extend the range of the data by the factor  $er.quasi.inv$  and compute an equi-spaced grid of points of length  $n.quasi.inv/2$  (e.g. using the default  $er.quasi.inv=1$  we go from the minimum data value minus  $1 \times$  the range to the maximum data value plus  $1 \times$  the range for each marginal). We then take these two grids, concatenate and sort, and these form the final grid of length  $n.quasi.inv$  for computing the quasi-inverse.

Note that if  $u$  is provided and any elements of (the columns of)  $u$  are such that they lie beyond the respective values of  $F$  for the evaluation data for the respective marginal, such values are reset to the minimum/maximum values of  $F$  for the respective marginal. It is therefore prudent to inspect the values of  $u$  returned by `npcopula` when  $u$  is provided.

Note that copula are only defined for data of type `numeric` or `ordered`.

## Value

`npcopula` returns an object of type `data.frame` with the following components

<code>copula</code>	the copula (bandwidth object obtained from <code>npudistbw</code> ) or copula density (bandwidth object obtained from <code>npudensbw</code> )
<code>u</code>	the matrix of marginal $u$ values associated with the sample realizations ( $u=NULL$ ) or those created via <code>expand.grid</code> when $u$ is provided
<code>data</code>	the matrix of marginal quantiles constructed when $u$ is provided (data returned has the same names as data inputted)

## Usage Issues

See the example below for proper usage.

```

---

npdeneqtest

---

*Kernel Consistent Density Equality Test with Mixed Data Types*

---

## Description

npdeneqtest implements a consistent integrated squared difference test for equality of densities as described in Li, Maasoumi, and Racine (2009).

## Usage

```

npdeneqtest(x = NULL,
            y = NULL,
            bw.x = NULL,
            bw.y = NULL,
            boot.num = 399,
            random.seed = 42,
            ...)

```

## Arguments

x, y	data frames for the two samples for which one wishes to test equality of densities. The variables in each data frame must be the same (i.e. have identical names).
------	--

<code>bw.x, bw.y</code>	optional bandwidth objects for <code>x, y</code>
<code>boot.num</code>	an integer value specifying the number of bootstrap replications to use. Defaults to 399.
<code>random.seed</code>	an integer used to seed R's random number generator. This is to ensure replicability. Defaults to 42.
<code>...</code>	additional arguments supplied to specify the bandwidth type, kernel types, and so on. This is used if you do not pass in bandwidth objects and you do not desire the default behaviours. To do this, you may specify any of <code>bwscaling</code> , <code>bwtype</code> , <code>ckertype</code> , <code>ckerorder</code> , <code>ukertype</code> , <code>okertype</code> .

### Details

`npdeneqtest` computes the integrated squared density difference between the estimated densities/probabilities of two samples having identical variables/datatypes. See Li, Maasoumi, and Racine (2009) for details.

### Value

`npdeneqtest` returns an object of type `deneqtest` with the following components

<code>Tn</code>	the (standardized) statistic <code>Tn</code>
<code>In</code>	the (unstandardized) statistic <code>In</code>
<code>Tn.bootstrap</code>	contains the bootstrap replications of <code>Tn</code>
<code>In.bootstrap</code>	contains the bootstrap replications of <code>In</code>
<code>Tn.P</code>	the P-value of the <code>Tn</code> statistic
<code>In.P</code>	the P-value of the <code>In</code> statistic
<code>boot.num</code>	number of bootstrap replications

[summary](#) supports object of type `deneqtest`.

### Usage Issues

If you are using data of mixed types, then it is advisable to use the [data.frame](#) function to construct your input data and not [cbind](#), since [cbind](#) will typically not work as intended on mixed data types and will coerce the data to the same type.

It is crucial that both data frames have the same variable names.

npdeneqtest(sample.A, sample.B, boot.num=99)

## End(Not run)
```

## Description

npdeptest implements the consistent metric entropy test of pairwise independence as described in Maasoumi and Racine (2002).

## Usage

```
npdeptest(data.x = NULL,
          data.y = NULL,
          method = c("integration", "summation"),
          bootstrap = TRUE,
          boot.num = 399,
          random.seed = 42)
```

## Arguments

data.x, data.y	two univariate vectors containing two variables that are of type <code>numeric</code> .
method	a character string used to specify whether to compute the integral version or the summation version of the statistic. Can be set as <code>integration</code> or <code>summation</code> (see below for details). Defaults to <code>integration</code> .
bootstrap	a logical value which specifies whether to conduct the bootstrap test or not. If set to <code>FALSE</code> , only the statistic will be computed. Defaults to <code>TRUE</code> .
boot.num	an integer value specifying the number of bootstrap replications to use. Defaults to 399.
random.seed	an integer used to seed R's random number generator. This is to ensure replicability. Defaults to 42.

## Details

npsdeptest computes the nonparametric metric entropy (normalized Hellinger of Granger, Maasoumi and Racine (2004)) for testing pairwise nonlinear dependence between the densities of two data series. See Maasoumi and Racine (2002) for details. Default bandwidths are of the Kullback-Leibler variety obtained via likelihood cross-validation. The null distribution is obtained via bootstrap resampling under the null of pairwise independence.

npdeptest computes the distance between the joint distribution and the product of marginals (i.e. the joint distribution under the null),  $D[f(y, \hat{y}), f(y) \times f(\hat{y})]$ . Examples include, (a) a measure/test of “fit”, for in-sample values of a variable  $y$  and its fitted values,  $\hat{y}$ , and (b) a measure of “predictability” for a variable  $y$  and its predicted values  $\hat{y}$  (from a user implemented model).

The summation version of this statistic will be numerically unstable when `data.x` and `data.y` lack common support or are sparse (the summation version involves division of densities while the integration version involves differences). Warning messages are produced should this occur (‘integration recommended’) and should be heeded.

## Value

npdeptest returns an object of type `deptest` with the following components

Srho	the statistic Srho
Srho.bootstrap.vec	contains the bootstrap replications of Srho
P	the P-value of the Srho statistic
bootstrap	a logical value indicating whether bootstrapping was performed
boot.num	number of bootstrap replications
bw.data.x	the numeric bandwidth for data.x marginal density
bw.data.y	the numeric bandwidth for data.y marginal density
bw.joint	the numeric matrix of bandwidths for data and lagged data joint density at lag num.lag

[summary](#) supports object of type `deptest`.

### Usage Issues

The integration version of the statistic uses multidimensional numerical methods from the **cubeature** package. See **adaptIntegrate** for details. The integration version of the statistic will be substantially slower than the summation version, however, it will likely be both more accurate and powerful.

---

npindex

---

*Semiparametric Single Index Model*

---

### Description

npindex computes a semiparametric single index model for a dependent variable and  $p$ -variate explanatory data using the model  $Y = G(X\beta) + \epsilon$ , given a set of evaluation points, training points

(consisting of explanatory data and dependent data), and a npindexbw bandwidth specification. Note that for this semiparametric estimator, the bandwidth object contains parameters for the single index model and the (scalar) bandwidth for the index function.

### Usage

```
npindex(bws, ...)

## S3 method for class 'formula'
npindex(bws,
        data = NULL,
        newdata = NULL,
        y.eval = FALSE,
        ...)

## S3 method for class 'call'
npindex(bws,
        ...)

## Default S3 method:
npindex(bws,
        txdat,
        tydat,
        ...)

## S3 method for class 'sibandwidth'
npindex(bws,
        txdat = stop("training data 'txdat' missing"),
        tydat = stop("training data 'tydat' missing"),
        exdat,
        eydat,
        gradients = FALSE,
        residuals = FALSE,
        errors = FALSE,
        boot.num = 399,
        ...)
```

### Arguments

bws	a bandwidth specification. This can be set as a sibandwidth object returned from an invocation of npindexbw, or as a vector of parameters (beta) with each element $i$ corresponding to the coefficient for column $i$ in txdat where the first element is normalized to 1, and a scalar bandwidth (h).
gradients	a logical value indicating that you want gradients and the asymptotic covariance matrix for beta computed and returned in the resulting singleindex object. Defaults to FALSE.
residuals	a logical value indicating that you want residuals computed and returned in the resulting singleindex object. Defaults to FALSE.

<code>errors</code>	a logical value indicating that you want (bootstrapped) standard errors for the conditional mean, gradients (when <code>gradients=TRUE</code> is set), and average gradients (when <code>gradients=TRUE</code> is set), computed and returned in the resulting <code>singleindex</code> object. Defaults to <code>FALSE</code> .
<code>boot.num</code>	an integer specifying the number of bootstrap replications to use when performing standard error calculations. Defaults to 399.
<code>...</code>	additional arguments supplied to specify the parameters to the <code>sibandwidth S3</code> method, which is called during estimation.
<code>data</code>	an optional data frame, list or environment (or object coercible to a data frame by <a href="#">as.data.frame</a> ) containing the variables in the model. If not found in <code>data</code> , the variables are taken from <code>environment(bws)</code> , typically the environment from which <code>npindexbw</code> was called.
<code>newdata</code>	An optional data frame in which to look for evaluation data. If omitted, the training data are used.
<code>y.eval</code>	If <code>newdata</code> contains dependent data and <code>y.eval = TRUE</code> , <code>np</code> will compute goodness of fit statistics on these data and return them. Defaults to <code>FALSE</code> .
<code>txdat</code>	a $p$ -variate data frame of explanatory data (training data) used to calculate the regression estimators. Defaults to the training data used to compute the bandwidth object.
<code>tydat</code>	a one (1) dimensional numeric or integer vector of dependent data, each element $i$ corresponding to each observation (row) $i$ of <code>txdat</code> . Defaults to the training data used to compute the bandwidth object.
<code>exdat</code>	a $p$ -variate data frame of points on which the regression will be estimated (evaluation data). By default, evaluation takes place on the data provided by <code>txdat</code> .
<code>eydat</code>	a one (1) dimensional numeric or integer vector of the true values of the dependent variable. Optional, and used only to calculate the true errors.

## Details

A matrix of gradients along with average derivatives are computed and returned if `gradients=TRUE` is used.

## Value

`npindex` returns a `npsingleindex` object. The generic functions [fitted](#), [residuals](#), [coef](#), [vcov](#), [se](#), [predict](#), and [gradients](#), extract (or generate) estimated values, residuals, coefficients, variance-covariance matrix, bootstrapped standard errors on estimates, predictions, and gradients, respectively, from the returned object. Furthermore, the functions [summary](#) and [plot](#) support objects of this type. The returned object has the following components:

<code>eval</code>	evaluation points
<code>mean</code>	estimates of the regression function (conditional mean) at the evaluation points
<code>beta</code>	the model coefficients
<code>betavcov</code>	the asymptotic covariance matrix for the model coefficients
<code>merr</code>	standard errors of the regression function estimates

<code>grad</code>	estimates of the gradients at each evaluation point
<code>gerr</code>	standard errors of the gradient estimates
<code>mean.grad</code>	mean (average) gradient over the evaluation points
<code>mean.gerr</code>	bootstrapped standard error of the mean gradient estimates
<code>R2</code>	if method="ichimura", coefficient of determination (Doksum and Samarov (1995))
<code>MSE</code>	if method="ichimura", mean squared error
<code>MAE</code>	if method="ichimura", mean absolute error
<code>MAPE</code>	if method="ichimura", mean absolute percentage error
<code>CORR</code>	if method="ichimura", absolute value of Pearson's correlation coefficient
<code>SIGN</code>	if method="ichimura", fraction of observations where fitted and observed values agree in sign
<code>confusion.matrix</code>	if method="kleinspady", the confusion matrix or NA if outcomes are not available
<code>CCR.overall</code>	if method="kleinspady", the overall correct classification ratio, or NA if outcomes are not available
<code>CCR.byoutcome</code>	if method="kleinspady", a numeric vector containing the correct classification ratio by outcome, or NA if outcomes are not available
<code>fit.mcfadden</code>	if method="kleinspady", the McFadden-Puig-Kerschner performance measure or NA if outcomes are not available

## Usage Issues

If you are using data of mixed types, then it is advisable to use the `data.frame` function to construct your input data and not `cbind`, since `cbind` will typically not work as intended on mixed data types and will coerce the data to the same type.

`vcov` requires that `gradients=TRUE` be set.

---

npindexbw	<i>Semiparametric Single Index Model Parameter and Bandwidth Selection</i>
-----------	--

---

## Description

npindexbw computes a npindexbw bandwidth specification using the model  $Y = G(X\beta) + \epsilon$ . For continuous  $Y$ , the approach is that of Hardle, Hall and Ichimura (1993) which jointly minimizes a least-squares cross-validation function with respect to the parameters and bandwidth. For binary  $Y$ , a likelihood-based cross-validation approach is employed which jointly maximizes a likelihood cross-validation function with respect to the parameters and bandwidth. The bandwidth object contains parameters for the single index model and the (scalar) bandwidth for the index function.

## Usage

```

npindexbw(...)

## S3 method for class 'formula'
npindexbw(formula, data, subset, na.action, call, ...)

```

```

## S3 method for class 'NULL'
npindexbw(xdat = stop("training data xdat missing"),
          ydat = stop("training data ydat missing"),
          bws,
          ...)

## Default S3 method:
npindexbw(xdat = stop("training data xdat missing"),
          ydat = stop("training data ydat missing"),
          bws,
          bandwidth.compute = TRUE,
          nmulti,
          random.seed,
          optim.method,
          optim.maxattempts,
          optim.reltol,
          optim.abstol,
          optim.maxit,
          only.optimize.beta,
          ...)

## S3 method for class 'sibandwidth'
npindexbw(xdat = stop("training data xdat missing"),
          ydat = stop("training data ydat missing"),
          bws,
          bandwidth.compute = TRUE,
          nmulti,
          random.seed = 42,
          optim.method = c("Nelder-Mead", "BFGS", "CG"),
          optim.maxattempts = 10,
          optim.reltol = sqrt(.Machine$double.eps),
          optim.abstol = .Machine$double.eps,
          optim.maxit = 500,
          only.optimize.beta = FALSE,
          ...)

```

## Arguments

formula	a symbolic description of variables on which bandwidth selection is to be performed. The details of constructing a formula are described below.
data	an optional data frame, list or environment (or object coercible to a data frame by <a href="#">as.data.frame</a> ) containing the variables in the model. If not found in data, the variables are taken from <code>environment(formula)</code> , typically the environment from which the function is called.
subset	an optional vector specifying a subset of observations to be used in the fitting process.
na.action	a function which indicates what should happen when the data contain NAs. The

	default is set by the <code>na.action</code> setting of options, and is <code>na.fail</code> if that is unset. The (recommended) default is <code>na.omit</code> .
<code>call</code>	the original function call. This is passed internally by <code>np</code> when a bandwidth search has been implied by a call to another function. It is not recommended that the user set this.
<code>xdat</code>	a $p$ -variate data frame of explanatory data (training data) used to calculate the regression estimators.
<code>ydat</code>	a one (1) dimensional numeric or integer vector of dependent data, each element $i$ corresponding to each observation (row) $i$ of <code>xdat</code> .
<code>bws</code>	a bandwidth specification. This can be set as a <code>singleindexbandwidth</code> object returned from an invocation of <code>npindexbw</code> , or as a vector of parameters (beta) with each element $i$ corresponding to the coefficient for column $i$ in <code>xdat</code> where the first element is normalized to 1, and a scalar bandwidth (h). If specified as a vector, then additional arguments will need to be supplied as necessary to specify the bandwidth type, kernel types, and so on.
<code>method</code>	the single index model method, one of either “ichimura” (Ichimura (1993)) or “kleinspady” (Klein and Spady (1993)). Defaults to <code>ichimura</code> .
<code>nmulti</code>	integer number of times to restart the process of finding extrema of the cross-validation function from different (random) initial points. Defaults to <code>min(5, ncol(xdat))</code> .
<code>random.seed</code>	an integer used to seed R’s random number generator. This ensures replicability of the numerical search. Defaults to 42.
<code>bandwidth.compute</code>	a logical value which specifies whether to do a numerical search for bandwidths or not. If set to <code>FALSE</code> , a bandwidth object will be returned with bandwidths set to those specified in <code>bws</code> . Defaults to <code>TRUE</code> .
<code>optim.method</code>	<p>method used by <code>optim</code> for minimization of the objective function. See <code>?optim</code> for references. Defaults to “Nelder-Mead”.</p> <p>the default method is an implementation of that of Nelder and Mead (1965), that uses only function values and is robust but relatively slow. It will work reasonably well for non-differentiable functions.</p> <p>method “BFGS” is a quasi-Newton method (also known as a variable metric algorithm), specifically that published simultaneously in 1970 by Broyden, Fletcher, Goldfarb and Shanno. This uses function values and gradients to build up a picture of the surface to be optimized.</p> <p>method “CG” is a conjugate gradients method based on that by Fletcher and Reeves (1964) (but with the option of Polak-Ribiere or Beale-Sorenson updates). Conjugate gradient methods will generally be more fragile than the BFGS method, but as they do not store a matrix they may be successful in much larger optimization problems.</p>
<code>optim.maxattempts</code>	maximum number of attempts taken trying to achieve successful convergence in <code>optim</code> . Defaults to 100.
<code>optim.abstol</code>	the absolute convergence tolerance used by <code>optim</code> . Only useful for non-negative functions, as a tolerance for reaching zero. Defaults to <code>.Machine\$double.eps</code> .

<code>optim.reltol</code>	relative convergence tolerance used by <code>optim</code> . The algorithm stops if it is unable to reduce the value by a factor of <code>'reltol * (abs(val) + reltol)'</code> at a step. Defaults to <code>sqrt(.Machine\$double.eps)</code> , typically about $1e-8$ .
<code>optim.maxit</code>	maximum number of iterations used by <code>optim</code> . Defaults to 500.
<code>only.optimize.beta</code>	signals the routine to only minimize the objective function with respect to beta
<code>...</code>	additional arguments supplied to specify the parameters to the <code>sibandwidth S3</code> method, which is called during the numerical search.

## Details

We implement Ichimura's (1993) method via joint estimation of the bandwidth and coefficient vector using leave-one-out nonlinear least squares. We implement Klein and Spady's (1993) method maximizing the leave-one-out log likelihood function jointly with respect to the bandwidth and coefficient vector. Note that Klein and Spady's (1993) method is for *binary outcomes only*, while Ichimura's (1993) method can be applied for any outcome data type (i.e., continuous or discrete).

We impose the identification condition that the first element of the coefficient vector beta is equal to one, while identification also requires that the explanatory variables contain *at least one* continuous variable.

`npindexbw` may be invoked *either* with a formula-like symbolic description of variables on which bandwidth selection is to be performed *or* through a simpler interface whereby data is passed directly to the function via the `xdat` and `ydat` parameters. Use of these two interfaces is **mutually exclusive**.

Note that, unlike most other bandwidth methods in the `np` package, this implementation uses the R `optim` nonlinear minimization routines and `npksum`. We have implemented multistarting and strongly encourage its use in practice. For exploratory purposes, you may wish to override the default search tolerances, say, setting `optim.reltol=.1` and conduct multistarting (the default is to restart `min(5, ncol(xdat))` times) as is done for a number of examples.

Data for which bandwidths are to be estimated may be specified symbolically. A typical description has the form `dependent data ~ explanatory data`, where dependent data is a univariate response, and explanatory data is a series of variables specified by name, separated by the separation character `'+'`. For example `y1 ~ x1 + x2` specifies that the bandwidth object for the regression of response `y1` and semiparametric regressors `x1` and `x2` are to be estimated. See below for further examples.

## Value

`npindexbw` returns a `sibandwidth` object, with the following components:

<code>bw</code>	bandwidth(s), scale factor(s) or nearest neighbours for the data, <code>xdat</code>
<code>beta</code>	coefficients of the model
<code>fval</code>	objective function value at minimum

If `bwtype` is set to `fixed`, an object containing a scalar bandwidth for the function  $G(X\beta)$  and an estimate of the parameter vector  $\beta$  is returned.

If `bwtype` is set to `generalized_nn` or `adaptive_nn`, then instead the scalar  $k$ th nearest neighbor is returned.

The functions `coef`, `predict`, `summary`, and `plot` support objects of this class.

## Usage Issues

If you are using data of mixed types, then it is advisable to use the `data.frame` function to construct your input data and not `cbind`, since `cbind` will typically not work as intended on mixed data types and will coerce the data to the same type.

Caution: multivariate data-driven bandwidth selection methods are, by their nature, *computationally intensive*. Virtually all methods require dropping the  $i$ th observation from the data set, computing an object, repeating this for all observations in the sample, then averaging each of these leave-one-out estimates for a *given* value of the bandwidth vector, and only then repeating this a large number of times in order to conduct multivariate numerical minimization/maximization. Furthermore, due to the potential for local minima/maxima, *restarting this procedure a large number of times may often be necessary*. This can be frustrating for users possessing large datasets. For exploratory purposes, you may wish to override the default search tolerances, say, setting `optim.reltol=.1` and conduct multistarting (the default is to restart `min(5, ncol(xdat))` times). Once the procedure terminates, you can restart search with default tolerances using those bandwidths obtained from the less rigorous search (i.e., set `bws=bw` on subsequent calls to this routine where `bw` is the initial bandwidth object). A version of this package using the `Rmpi` wrapper is under development that allows one to deploy this software in a clustered computing environment to facilitate computation involving large datasets.

## Arguments

formula	a symbolic description of variables on which the sum is to be performed. The details of constructing a formula are described below.
data	an optional data frame, list or environment (or object coercible to a data frame by <a href="#">as.data.frame</a> ) containing the variables in the model. If not found in data, the variables are taken from <code>environment(formula)</code> , typically the environment from which the function is called.
newdata	An optional data frame in which to look for evaluation data. If omitted, data is used.
subset	an optional vector specifying a subset of observations to be used.
na.action	a function which indicates what should happen when the data contain NAs. The default is set by the <a href="#">na.action</a> setting of options, and is <a href="#">na.fail</a> if that is unset. The (recommended) default is <a href="#">na.omit</a> .

...	additional arguments supplied to specify the parameters to the default S3 method, which is called during estimation.
txdat	a $p$ -variate data frame of sample realizations (training data) used to compute the sum.
tydat	a numeric vector of data to be weighted. The $i$ th kernel weight is applied to the $i$ th element. Defaults to 1.
exdat	a $p$ -variate data frame of sum evaluation points (if omitted, defaults to the training data itself).
bws	a bandwidth specification. This can be set as any suitable bandwidth object returned from a bandwidth-generating function, or a numeric vector.
weights	a $n$ by $q$ matrix of weights which can optionally be applied to tydat in the sum. See details.
leave.one.out	a logical value to specify whether or not to compute the leave one out sums. Will not work if exdat is specified. Defaults to FALSE.
kernel.pow	an integer specifying the power to which the kernels will be raised in the sum. Defaults to 1.
bandwidth.divide	a logical specifying whether or not to divide continuous kernel weights by their bandwidths. Use this with nearest-neighbor methods. Defaults to FALSE.
operator	a string specifying whether the normal, convolution, derivative, or integral kernels are to be used. Operators scale results by factors of $h$ or $1/h$ where appropriate. Defaults to normal and applies to all elements in a multivariate object. See details.
permutation.operator	a string which can have a value of none, normal, derivative, or integral. If set to something other than none (the default), then a separate result will be returned for each term in the product kernel, with the operator applied to that term. Permutation operators scale results by factors of $h$ or $1/h$ where appropriate. This is useful for computing gradients, for example.
compute.score	a logical specifying whether or not to return the score (the 'grad h' terms) for each dimension in addition to the kernel sum. Cannot be TRUE if a permutation operator other than "none" is selected.
compute.ocg	a logical specifying whether or not to return a separate result for each unordered and ordered dimension, where the product kernel term for that dimension is evaluated at an appropriate reference category. This is used primarily in np to compute ordered and unordered categorical gradients. See details.
return.kernel.weights	a logical specifying whether or not to return the matrix of generalized product kernel weights. Defaults to FALSE. See details.

## Details

npksum exists so that you can create your own kernel objects with or without a variable to be weighted (default  $Y = 1$ ). With the options available, you could create new nonparametric tests or even new kernel estimators. The convolution kernel option would allow you to create, say, the least squares cross-validation function for kernel density estimation.

npksum uses highly-optimized C code that strives to minimize its ‘memory footprint’, while there is low overhead involved when using repeated calls to this function (see, by way of illustration, the example below that conducts leave-one-out cross-validation for a local constant regression estimator via calls to the R function `nlm`, and compares this to the `npregbw` function).

npksum implements a variety of methods for computing multivariate kernel sums ( $p$ -variate) defined over a set of possibly continuous and/or discrete (unordered, ordered) data. The approach is based on Li and Racine (2003) who employ ‘generalized product kernels’ that admit a mix of continuous and discrete data types.

Three classes of kernel estimators for the continuous data types are available: fixed, adaptive nearest-neighbor, and generalized nearest-neighbor. Adaptive nearest-neighbor bandwidths change with each sample realization in the set,  $x_i$ , when estimating the kernel sum at the point  $x$ . Generalized nearest-neighbor bandwidths change with the point at which the sum is computed,  $x$ . Fixed bandwidths are constant over the support of  $x$ .

npksum computes  $\sum_{j=1}^n W_j' Y_j K(X_j)$ , where  $W_j$  represents a row vector extracted from  $W$ . That is, it computes the kernel weighted sum of the outer product of the rows of  $W$  and  $Y$ . In the examples, the uses of such sums are illustrated.

npksum may be invoked *either* with a formula-like symbolic description of variables on which the sum is to be performed *or* through a simpler interface whereby data is passed directly to the function via the `txdat` and `tydat` parameters. Use of these two interfaces is **mutually exclusive**.

Data contained in the data frame `txdat` (and also `exdat`) may be a mix of continuous (default), unordered discrete (to be specified in the data frame `txdat` using the `factor` command), and ordered discrete (to be specified in the data frame `txdat` using the `ordered` command). Data can be entered in an arbitrary order and data types will be detected automatically by the routine (see `np` for details).

Data for which bandwidths are to be estimated may be specified symbolically. A typical description has the form `dependent data ~ explanatory data`, where dependent data and explanatory data are both series of variables specified by name, separated by the separation character ‘+’. For example, `y1 ~ x1 + x2` specifies that `y1` is to be kernel-weighted by `x1` and `x2` throughout the sum. See below for further examples.

A variety of kernels may be specified by the user. Kernels implemented for continuous data types include the second, fourth, sixth, and eighth order Gaussian and Epanechnikov kernels, and the uniform kernel. Unordered discrete data types use a variation on Aitchison and Aitken’s (1976) kernel, while ordered data types use a variation of the Wang and van Ryzin (1981) kernel (see `np` for details).

The option `operator=` can be used to ‘mix and match’ operator strings to create a ‘hybrid’ kernel provided they match the dimension of the data. For example, for a two-dimensional data frame of `numeric` datatypes, `operator=c("normal", "derivative")` will use the normal (i.e. PDF) kernel for variable one and the derivative of the PDF kernel for variable two. Please note that applying operators will scale the results by factors of  $h$  or  $1/h$  where appropriate.

The option `permutation.operator=` can be used to ‘mix and match’ operator strings to create a ‘hybrid’ kernel, in addition to the kernel sum with no operators applied, one for each continuous dimension in the data. For example, for a two-dimensional data frame of `numeric` datatypes, `permutation.operator=c("derivative")` will return the usual kernel sum as if `operator = c("normal", "normal")` in the `ksum` member, and in the `p.ksum` member, it will return kernel sums for `operator = c("derivative", "normal")`, and `operator = c("normal", "derivative")`. This makes the computation of gradients much easier.

The option `compute.score=` can be used to compute the gradients with respect to  $h$  in addition to the normal kernel sum. Like permutations, the additional results are returned in the `p.ksum`. This option does not work in conjunction with `permutation.operator`.

The option `compute.ocg=` works much like `permutation.operator`, but for discrete variables. The kernel is evaluated at a reference category in each dimension: for ordered data, the next lowest category is selected, except in the case of the lowest category, where the second lowest category is selected; for unordered data, the first category is selected. These additional data are returned in the `p.ksum` member. This option can be set simultaneously with `permutation.operator`.

The option `return.kernel.weights=TRUE` returns a matrix of dimension ‘number of training observations’ by ‘number of evaluation observations’ and contains only the generalized product kernel weights ignoring all other objects and options that may be provided to `npksum` (e.g. `bandwidth.divide=TRUE` will be ignored, etc.). Summing the columns of the weight matrix and dividing by ‘number of training observations’ times the product of the bandwidths (i.e. `colMeans(foo$kw)/prod(h)`) would produce the kernel estimator of a (multivariate) density (`operator="normal"`) or multivariate cumulative distribution (`operator="integral"`).

## Value

`npksum` returns a `npkernelsum` object with the following components:

<code>eval</code>	the evaluation points
<code>ksum</code>	the sum at the evaluation points
<code>kw</code>	the kernel weights (when <code>return.kernel.weights=TRUE</code> is specified)

## Usage Issues

If you are using data of mixed types, then it is advisable to use the `data.frame` function to construct your input data and not `cbind`, since `cbind` will typically not work as intended on mixed data types and will coerce the data to the same type.

## Examples

```
## Not run:
# EXAMPLE 1: For this example, we generate 100,000 observations from a
# N(0, 1) distribution, then evaluate the kernel density on a grid of 50
# equally spaced points using the npksum() function, then compare
# results with the (identical) npudens() function output

n <- 100000
x <- rnorm(n)
x.eval <- seq(-4, 4, length=50)

# Compute the bandwidth with the normal-reference rule-of-thumb

bw <- npudensbw(dat=x, bwmethod="normal-reference")

# Compute the univariate kernel density estimate using the 100,000
# training data points evaluated on the 50 evaluation data points,
# i.e., 1/nh times the sum of the kernel function evaluated at each of
# the 50 points

den.ksum <- npksum(txdat=x, exdat=x.eval, bws=bw$bw)$ksum/(n*bw$bw[1])

# Note that, alternatively (easier perhaps), you could use the
# bandwidth.divide=TRUE argument and drop the *bw$bw[1] term in the
# denominator, as in
# npksum(txdat=x, exdat=x.eval, bws=bw$bw, bandwidth.divide=TRUE)$ksum/n

# Compute the density directly with the npudens() function...

den <- fitted(npudens(tdat=x, edat=x.eval, bws=bw$bw))

# Plot the true DGP, the npksum()/(nh) estimate and (identical)
# npudens() estimate

plot(x.eval, dnorm(x.eval), xlab="X", ylab="Density", type="l")
points(x.eval, den.ksum, col="blue")
points(x.eval, den, col="red", cex=0.2)
legend(1, .4,
      c("DGP", "npksum()",
        "npudens()"),
      col=c("black", "blue", "red"),
      lty=c(1, 1, 1))

# Sleep for 5 seconds so that we can examine the output...

Sys.sleep(5)

# EXAMPLE 2: For this example, we first obtain residuals from a
# parametric regression model, then compute a vector of leave-one-out
# kernel weighted sums of squared residuals where the kernel function is
# raised to the power 2. Note that this returns a vector of kernel
# weighted sums, one for each element of the error vector. Note also
```

```
# that you can specify the bandwidth type, kernel function, kernel order
# etc.

data("cps71")

ksum <- npksum(txdat=age,
               tydat=error^2,
               bws=bw$bw,
               leave.one.out=TRUE,
               kernel.pow=2)

ksum

# Obviously, if we wanted the sum of these weighted kernel sums then,
# trivially,

sum(ksum$ksum)

detach(cps71)

# Sleep for 5 seconds so that we can examine the output...

Sys.sleep(5)

# Note that weighted leave-one-out sums of squared residuals are used to
# construct consistent model specification tests. In fact, the
# npcmstest() routine in this package is constructed purely from calls
# to npksum(). You can type npcmstest to see the npcmstest()
# code and also examine some examples of the many uses of
# npksum().

# EXAMPLE 3: For this example, we conduct local-constant (i.e.,
# Nadaraya-Watson) kernel regression. We shall use cross-validated
# bandwidths using npregbw() by way of example. Note we extract
# the kernel sum from npksum() via the `ksum' argument in both
# the numerator and denominator.

data("cps71")
attach(cps71)

bw <- npregbw(xdat=age, ydat=logwage)

fit.lc <- npksum(txdat=age, tydat=logwage, bws=bw$bw)$ksum/
        npksum(txdat=age, bws=bw$bw)$ksum

plot(age, logwage, xlab="Age", ylab="log(wage)")
lines(age, fit.lc)
```

```

# Sleep for 5 seconds so that we can examine the output...

Sys.sleep(5)

# If you wished to compute the kernel sum for a set of evaluation points,
# you first generate the set of points then feed this to npksum,
# e.g., for the set (20, 30, ..., 60) we would use

age.seq <- seq(20, 60, 10)

fit.lc <- npksum(txdat=age, exdat=age.seq, tydat=logwage, bws=bw$bw)$ksum/
      npksum(txdat=age, exdat=age.seq, bws=bw$bw)$ksum

# Note that now fit.lc contains the 5 values of the local constant
# estimator corresponding to age.seq...

fit.lc

detach(cps71)

# EXAMPLE 4: For this example, we conduct least-squares cross-validation
# for the local-constant regression estimator. We first write an R
# function 'ss' that computes the leave-one-out sum of squares using the
# npksum() function, and then feed this function, along with
# random starting values for the bandwidth vector, to the nlm() routine
# in R (nlm = Non-Linear Minimization). Finally, we compare results with
# the function npregbw() that is written solely in C and calls
# a tightly coupled C-level search routine. Note that one could make
# repeated calls to nlm() using different starting values for h (highly
# recommended in general).

# Increase the number of digits printed out by default in R and avoid
# using scientific notation for this example (we wish to compare
# objective function minima)

options(scipen=100, digits=12)

# Generate 100 observations from a simple DGP where one explanatory
# variable is irrelevant.

n <- 100

x1 <- runif(n)
x2 <- rnorm(n)
x3 <- runif(n)

txdat <- data.frame(x1, x2, x3)

# Note - x3 is irrelevant

tydat <- x1 + sin(x2) + rnorm(n)

# Write an R function that returns the average leave-one-out sum of

```

```

# squared residuals for the local constant estimator based upon
# npksum(). This function accepts one argument and presumes that
# txdat and tydat have been defined already.

ss <- function(h) {

# Test for valid (non-negative) bandwidths - return infinite penalty
# when this occurs

  if(min(h)<=0) {

    return(.Machine$double.xmax)

  } else {

    mean <- npksum(txdat,
                    tydat,
                    leave.one.out=TRUE,
                    bandwidth.divide=TRUE,
                    bws=h)$ksum/
    npksum(txdat,
            leave.one.out=TRUE,
            bandwidth.divide=TRUE,
            bws=h)$ksum

    return(sum((tydat-mean)^2)/length(tydat))

  }

}

# Now pass this function to R's nlm() routine along with random starting
# values and place results in `nlm.return'.

nlm.return <- nlm(ss, runif(length(txdat)))

bw <- npregbw(xdat=txdat, ydat=tydat)

# Bandwidths from nlm()

nlm.return$estimate

# Bandwidths from npregbw()

npplot

*General Purpose Plotting of Nonparametric Objects*

---

## Description

npplot is invoked by `plot` and generates plots of nonparametric statistical objects such as regressions, quantile regressions, partially linear regressions, single-index models, densities and distributions, given training data and a bandwidth object.

## Usage

```

npplot(bws = stop("'bws' has not been set"), ..., random.seed = 42)

## S3 method for class 'bandwidth'
npplot(bws,
       xdat,

## Arguments

bws	a bandwidth specification. This should be a bandwidth object returned from an invocation of <a href="#">npudensbw</a> , <a href="#">npcdensbw</a> , <a href="#">npregbw</a> , <a href="#">npplregbw</a> , <a href="#">npindexbw</a> , or <a href="#">npscoefbw</a> .
...	additional arguments supplied to control various aspects of plotting, depending on the type of object to be plotted, detailed below.
data	an optional data frame, list or environment (or object coercible to a data frame by <a href="#">as.data.frame</a> ) containing the variables in the model. If not found in data, the variables are taken from <code>environment(bws)</code> , typically the environment where the bandwidth object was generated.
xdat	a $p$ -variate data frame of sample realizations (training data).
ydat	a $q$ -variate data frame of sample realizations (training data). In a regression or conditional density context, this is the dependent data.
zdat	a $p$ -variate data frame of sample realizations (training data).

<code>xq</code>	a numeric $p$ -vector of quantiles. Each element $i$ of <code>xq</code> corresponds to the $i$ th column of <code>txdat</code> . Defaults to the median (0.5). See details.
<code>yq</code>	a numeric $q$ -vector of quantiles. Each element $i$ of <code>yq</code> corresponds to the $i$ th column of <code>tydat</code> . Only to be specified in a conditional density context. Defaults to the median (0.5). See details.
<code>zq</code>	a numeric $q$ -vector of quantiles. Each element $i$ of <code>zq</code> corresponds to the $i$ th column of <code>tzdat</code> . Only to be specified in a semiparametric model context. Defaults to the median (0.5). See details.
<code>xtrim</code>	a numeric $p$ -vector of quantiles. Each element $i$ of <code>xtrim</code> corresponds to the $i$ th column of <code>txdat</code> . Defaults to $\emptyset$ . $\emptyset$ . See details.
<code>ytrim</code>	a numeric $q$ -vector of quantiles. Each element $i$ of <code>ytrim</code> corresponds to the $i$ th column of <code>tydat</code> . Defaults to $\emptyset$ . $\emptyset$ . See details.
<code>ztrim</code>	a numeric $q$ -vector of quantiles. Each element $i$ of <code>ztrim</code> corresponds to the $i$ th column of <code>tzdat</code> . Defaults to $\emptyset$ . $\emptyset$ . See details.
<code>neval</code>	an integer specifying the number of evaluation points. Only applies to continuous variables however, as discrete variables will be evaluated once at each category. Defaults to 50.
<code>common.scale</code>	a logical value specifying whether or not all graphs are to be plotted on a common scale. Defaults to TRUE.
<code>perspective</code>	a logical value specifying whether a perspective plot should be displayed (if possible). Defaults to TRUE.
<code>gradients</code>	a logical value specifying whether gradients should be plotted (if possible). Defaults to FALSE.
<code>main</code>	optional title, see <a href="#">title</a> . Defaults to NULL.
<code>sub</code>	optional subtitle, see <a href="#">sub</a> . Defaults to NULL.
<code>type</code>	optional character indicating the type of plotting; actually any of the types as in <a href="#">plot.default</a> . Defaults to NULL.
<code>border</code>	optional character indicating the border of plotting; actually any of the borders as in <a href="#">plot.default</a> . Defaults to NULL.
<code>cex.axis</code>	The magnification to be used for axis annotation relative to the current setting of <code>cex</code> .
<code>cex.lab</code>	The magnification to be used for x and y labels relative to the current setting of <code>cex</code> .
<code>cex.main</code>	The magnification to be used for main titles relative to the current setting of <code>cex</code> .
<code>cex.sub</code>	The magnification to be used for sub-titles relative to the current setting of <code>cex</code> .
<code>col</code>	optional character indicating the color of plotting; actually any of the colours as in <a href="#">plot.default</a> . Defaults to NULL.
<code>ylab</code>	optional character indicating the y axis label of plotting; actually any of the ylabs as in <a href="#">plot.default</a> . Defaults to NULL.
<code>xlab</code>	optional character indicating the x axis label of plotting; actually any of the xlabs as in <a href="#">plot.default</a> . Defaults to NULL.
<code>zlab</code>	optional character indicating the z axis label of plotting; actually any of the zlabs as in <a href="#">plot.default</a> . Defaults to NULL.

<code>ylim</code>	optional a two-element numeric vector of the minimum and maximum y plotting limits. Defaults to NULL.
<code>xlim</code>	a two-element numeric vector of the minimum and maximum x plotting limits. Defaults to NULL.
<code>zlim</code>	a two-element numeric vector of the minimum and maximum z plotting limits. Defaults to NULL.
<code>lty</code>	a numeric value indicating the line type of plotting; actually any of the ltys as in <a href="#">plot.default</a> . Defaults to 1.
<code>lwd</code>	a numeric value indicating the width of the line of plotting; actually any of the lwds as in <a href="#">plot.default</a> . Defaults to 1.
<code>theta</code>	a numeric value specifying the starting azimuthal angle of the perspective plot. Defaults to 0.0.
<code>phi</code>	a numeric value specifying the starting zenith angle of the perspective plot. Defaults to 10.0.
<code>tau</code>	a numeric value specifying the $\tau$ th quantile is desired when plotting quantile regressions. Defaults to 0.5.
<code>view</code>	a character string used to specify the viewing mode of the perspective plot. Can be set as rotate or fixed. Defaults to rotate.
<code>plot.behavior</code>	a character string used to specify the net behavior of npplot. Can be set as plot, plot-data or data. Defaults to plot. See value.
<code>plot.errors.method</code>	a character string used to specify the method to calculate errors. Can be set as none, bootstrap, or asymptotic. Defaults to none.
<code>plot.errors.boot.method</code>	a character string used to specify the bootstrap method. Can be set as inid, fixed, or geom (see below for details). Defaults to inid.
<code>plot.errors.boot.blocklen</code>	an integer used to specify the block length $b$ for the fixed or geom bootstrap (see below for details).
<code>plot.errors.boot.num</code>	an integer used to specify the number of bootstrap samples to use for the calculation of errors. Defaults to 399.
<code>plot.errors.center</code>	a character string used to specify where to center the errors on the plot(s). Can be set as estimate or bias-corrected. Defaults to estimate.
<code>plot.errors.type</code>	a character string used to specify the type of error to calculate. Can be set as standard or quantiles. Defaults to standard.
<code>plot.errors.quantiles</code>	a numeric vector specifying the quantiles of the statistic to calculate for the purpose of error plotting. Defaults to <code>c(0.025, 0.975)</code> .
<code>plot.errors.style</code>	a character string used to specify the style of error plotting. Can be set as band or bar. Defaults to band. Bands are not drawn for discrete variables.

<code>plot.errors.bar</code>	a character string used to specify the error bar shape. Can be set as <code> </code> (vertical bar character) for a dashed vertical bar, or as <code>I</code> for an ‘I’ shaped error bar with horizontal bounding bars. Defaults to <code> </code> .
<code>plot.errors.bar.num</code>	an integer specifying the number of error bars to plot. Defaults to <code>min(neval, 25)</code> .
<code>plot.bxp</code>	a logical value specifying whether boxplots should be produced when appropriate. Defaults to <code>FALSE</code> .
<code>plot.bxp.out</code>	a logical value specifying whether outliers should be plotted on boxplots. Defaults to <code>TRUE</code> .
<code>plot.par.mfrow</code>	a logical value specifying whether <code>par(mfrow=c(,))</code> should be called before plotting. Defaults to <code>TRUE</code> .
<code>random.seed</code>	an integer used to seed R’s random number generator. This ensures replicability of the bootstrapped errors. Defaults to 42.

## Details

npplot is a general purpose plotting routine for visually exploring objects generated by the `np` library, such as regressions, quantile regressions, partially linear regressions, single-index models, densities and distributions. There is no need to call `npplot` directly as it is automatically invoked when `plot` is used with an object generated by the `np` package.

Visualizing one and two dimensional datasets is a straightforward process. The default behavior of `npplot` is to generate a standard 2D plot to visualize univariate data, and a perspective plot for bivariate data. When visualizing higher dimensional data, `npplot` resorts to plotting a series of 1D slices of the data. For a slice along dimension  $i$ , all other variables at indices  $j \neq i$  are held constant at the quantiles specified in the  $j$ th element of `xq`. The default is the median.

The slice itself is evaluated on a uniformly spaced sequence of `neval` points. The interval of evaluation is determined by the training data. The default behavior is to evaluate from `min(txdat[,i])` to `max(txdat[,i])`. The `xtrim` variable allows for control over this behavior. When `xtrim` is set, data is evaluated from the `xtrim[i]`th quantile of `txdat[,i]` to the `1.0-xtrim[i]`th quantile of `txdat[,i]`.

Furthermore, `xtrim` can be set to a negative value in which case it will expand the limits of the evaluation interval beyond the support of the training data, by measuring the distance between `min(txdat[,i])` and the `xtrim[i]`th quantile of `txdat[,i]`, and extending the support by that distance on the lower limit of the interval. `npplot` uses an analogous procedure to extend the upper limit of the interval.

Bootstrap resampling is conducted pairwise on  $(y, X, Z)$  (i.e., by resampling from rows of the  $(y, X)$  data or  $(y, X, Z)$  data where appropriate). `inid` admits general heteroskedasticity of unknown form, though it does not allow for dependence. `fixed` conducts Kunsch’s (1988) block bootstrap for dependent data, while `geom` conducts Politis and Romano’s (1994) stationary bootstrap.

For consistency of the block and stationary bootstrap, the (mean) block length  $b$  should grow with the sample size  $n$  at an appropriate rate. If  $b$  is not given, then a default growth rate of  $const \times n^{1/3}$  is used. This rate is “optimal” under certain conditions (see Politis and Romano (1994) for more details). However, in general the growth rate depends on the specific properties of the DGP. A default value for `const` (3.15) has been determined by a Monte Carlo simulation using a Gaussian

AR(1) process (AR(1)-parameter of 0.5, 500 observations). *const* has been chosen such that the mean square error for the bootstrap estimate of the variance of the empirical mean is minimized.

## Value

Setting `plot.behavior` will instruct npplot what data to return. Option summary:

`plot`: instruct npplot to just plot the data and return NULL

`plot-data`: instruct npplot to plot the data and return the data used to generate the plots. The data will be a list of objects of the appropriate type, with one object per plot. For example, invoking npplot on 3D density data will have it return a list of three `npdensity` objects. If biases were calculated, they are stored in a component named `bias`

`data`: instruct npplot to generate data only and no plots

## Usage Issues

If you are using data of mixed types, then it is advisable to use the `data.frame` function to construct your input data and not `cbind`, since `cbind` will typically not work as intended on mixed data types and will coerce the data to the same type.

## Examples

```
## Not run:
# EXAMPLE 1: For this example, we load Giovanni Baiocchi's Italian GDP
# panel (see Italy for details), then create a data frame in which year
```

```
# is an ordered factor, GDP is continuous, compute bandwidths using
# likelihood cross-validation, then create a grid of data on which the
# density will be evaluated for plotting purposes

data("Italy")
attach(Italy)

data <- data.frame(ordered(year), gdp)

# Compute bandwidths using likelihood cross-validation (default). Note
# that this may take a minute or two depending on the speed of your
# computer...

bw <- npudensbw(dat=data)

# You can always do things manually, as the following example demonstrates

# Create an evaluation data matrix

year.seq <- sort(unique(year))
gdp.seq <- seq(1,36,length=50)
data.eval <- expand.grid(year=year.seq,gdp=gdp.seq)

# Generate the estimated density computed for the evaluation data

fhat <- fitted(npudens(tdat = data, edat = data.eval, bws=bw))

# Coerce the data into a matrix for plotting with persp()

f <- matrix(fhat, length(unique(year)), 50)

# Next, create a 3D perspective plot of the PDF f

persp(as.integer(levels(year.seq)), gdp.seq, f, col="lightblue",
      ticktype="detailed", ylab="GDP", xlab="Year", zlab="Density",
      theta=300, phi=50)

# Sleep for 5 seconds so that we can examine the output...

Sys.sleep(5)

# However, npplot simply streamlines this process and aids in the
# visualization process (<ctrl>-C will interrupt on *NIX systems, <esc>
# will interrupt on MS Windows systems).

plot(bw)

# npplot also streamlines construction of variability bounds (<ctrl>-C
# will interrupt on *NIX systems, <esc> will interrupt on MS Windows
# systems)

plot(bw, plot.errors.method = "asymptotic")
```

```

# EXAMPLE 2: For this example, we simulate multivariate data, and plot the
# partial regression surfaces for a locally linear estimator and its
# derivatives.

set.seed(123)

n <- 100

x1 <- runif(n)
x2 <- runif(n)
x3 <- runif(n)
x4 <- rbinom(n, 2, .3)

y <- 1 + x1 + x2 + x3 + x4 + rnorm(n)

X <- data.frame(x1, x2, x3, ordered(x4))

bw <- npregbw(xdat=X, ydat=y, regtype="ll", bwmethod="cv.aic")

plot(bw)

# Sleep for 5 seconds so that we can examine the output...

Sys.sleep(5)

# Now plot the gradients...

plot(bw, gradients=TRUE)

# Plot the partial regression surfaces with bias-corrected bootstrapped
# nonparametric confidence intervals... this may take a minute or two
# depending on the speed of your computer as the bootstrapping must be
# completed prior to results being displayed...

plot(bw,
      plot.errors.method="bootstrap",
      plot.errors.center="bias-corrected",
      plot.errors.type="quantiles")

# Note - if you wished to create, say, a postscript graph for inclusion
# in, say, a latex document, use R's `postscript' command to switch to
# the postscript device (turn off the device once completed). The
# following will create a disk file `graph.ps' that can be pulled into,
# say, a latex document via \includegraphics[width=5in, height=5in,
# angle=270]{graph.ps}

# Note - make sure to include the graphicx package in your latex
# document via adding \usepackage{graphicx} in your latex file. Also,
# you might want to use larger fonts, which can be achieved by adding the
# pointsize= argument, e.g., postscript(file="graph.ps", pointsize=20)

postscript(file="graph.ps")
plot(bw)

```

```

dev.off()

# The following latex file compiled in the same directory as graph.ps
# ought to work (remove the #s and place in a file named, e.g.,
# test.tex).
# \documentclass[]{article}
# \usepackage{graphicx}
# \begin{document}
# \begin{figure}[!ht]
# \includegraphics[width=5in, height=5in, angle=270]{graph.ps}
# \caption{Local linear partial regression surfaces.}
# \end{figure}
# \end{document}

# EXAMPLE 3: This example demonstrates how to retrieve plotting data from
# npplot(). When npplot() is called with the arguments
# `plot.behavior="plot-data"' (or "data"), it returns plotting objects
# named r1, r2, and so on (rg1, rg2, and so on when `gradients=TRUE' is
# set). Each plotting object's index (1,2,...) corresponds to the index
# of the explanatory data data frame xdat (and zdat if appropriate).

# Take the cps71 data by way of example. In this case, there is only one
# object returned by default, `r1', since xdat is univariate.

data("cps71")
attach(cps71)

# Compute bandwidths for local linear regression using cv.aic...

bw <- npregbw(xdat=age,ydat=logwage,regtype="ll",bwmethod="cv.aic")

# Generate the plot and return plotting data, and store output in
# `plot.out' (NOTE: the call to `plot.behavior' is necessary).

plot.out <- plot(bw,
                 perspective=FALSE,
                 plot.errors.method="bootstrap",
                 plot.errors.boot.num=25,
                 plot.behavior="plot-data")

# Now grab the r1 object that npplot plotted on the screen, and take
# what you need. First, take the output, lower error bound and upper
# error bound...

logwage.eval <- fitted(plot.out$r1)
logwage.se <- se(plot.out$r1)
logwage.lower.ci <- logwage.eval + logwage.se[,1]
logwage.upper.ci <- logwage.eval + logwage.se[,2]

# Next grab the x data evaluation data. xdat is a data.frame(), so we
# need to coerce it into a vector (take the `first column' of data frame
# even though there is only one column)

```

```

age.eval <- plot.out$r1$eval[,1]

# Now we could plot this if we wished, or direct it to whatever end use
# we envisioned. We plot the results using R's plot() routines...

plot(age, logwage, cex=0.2, xlab="Age", ylab="log(Wage)")
lines(age.eval, logwage.eval)
lines(age.eval, logwage.lower.ci, lty=3)
lines(age.eval, logwage.upper.ci, lty=3)

# If you wanted npplot() data for gradients, you would use the argument
# `gradients=TRUE' in the call to npplot() as the following
# demonstrates...

plot.out <- plot(bw,
                 perspective=FALSE,
                 plot.errors.method="bootstrap",
                 plot.errors.boot.num=25,
                 plot.behavior="plot-data",
                 gradients=TRUE)

# Now grab object that npplot() plotted on the screen. First, take the
# output, lower error bound and upper error bound... note that gradients
# are stored in objects rg1, rg2 etc.

grad.eval <- gradients(plot.out$rg1)
grad.se <- gradients(plot.out$rg1, errors = TRUE)
grad.lower.ci <- grad.eval + grad.se[,1]
grad.upper.ci <- grad.eval + grad.se[,2]

# Next grab the x evaluation data. xdat is a data.frame(), so we need to
# coerce it into a vector (take `first column' of data frame even though
# there is only one column)

age.eval <- plot.out$rg1$eval[,1]

# We plot the results using R's plot() routines...

plot(age.eval, grad.eval, cex=0.2,
      ylim=c(min(grad.lower.ci), max(grad.upper.ci)),
      xlab="Age", ylab="d log(Wage)/d Age", type="l")
lines(age.eval, grad.lower.ci, lty=3)
lines(age.eval, grad.upper.ci, lty=3)

detach(cps71)

## End(Not run)

```

## Description

npplreg computes a partially linear kernel regression estimate of a one (1) dimensional dependent variable on  $p + q$ -variate explanatory data, using the model  $Y = X\beta + \Theta(Z) + \epsilon$  given a set of estimation points, training points (consisting of explanatory data and dependent data), and a bandwidth specification, which can be a rbandwidth object, or a bandwidth vector, bandwidth type and kernel type.

## Usage

```
npplreg(bws, ...)

## S3 method for class 'formula'
npplreg(bws, data = NULL, newdata = NULL, y.eval =
FALSE, ...)

## S3 method for class 'call'
npplreg(bws, ...)

## S3 method for class 'plbandwidth'
npplreg(bws,
        txdat = stop("training data txdat missing"),
        tydat = stop("training data tydat missing"),
        tzdat = stop("training data tzdat missing"),
        exdat,
        eydat,
        ezdat,
        residuals = FALSE,
        ...)
```

## Arguments

bws	a bandwidth specification. This can be set as a plbandwidth object returned from an invocation of <a href="#">npplregbw</a> , or as a matrix of bandwidths, where each row is a set of bandwidths for $Z$ , with a column for each variable $Z_i$ . In the first row are the bandwidths for the regression of $Y$ on $Z$ , the following rows contain the bandwidths for the regressions of the columns of $X$ on $Z$ . If specified as a matrix additional arguments will need to be supplied as necessary to specify the bandwidth type, kernel types, training data, and so on.
...	additional arguments supplied to specify the regression type, bandwidth type, kernel types, selection methods, and so on. To do this, you may specify any of regtype, bwmethod, bwscaling, bwtype, ckertype, ckerorder, ukertype, okertype, as described in <a href="#">npregbw</a> .
data	an optional data frame, list or environment (or object coercible to a data frame by <a href="#">as.data.frame</a> ) containing the variables in the model. If not found in data, the variables are taken from environment(bws), typically the environment from which <a href="#">npplregbw</a> was called.
newdata	An optional data frame in which to look for evaluation data. If omitted, the training data are used.

<code>y.eval</code>	If <code>newdata</code> contains dependent data and <code>y.eval = TRUE</code> , <code>np</code> will compute goodness of fit statistics on these data and return them. Defaults to <code>FALSE</code> .
<code>txdat</code>	a $p$ -variate data frame of explanatory data (training data), corresponding to $X$ in the model equation, whose linear relationship with the dependent data $Y$ is posited. Defaults to the training data used to compute the bandwidth object.
<code>tydat</code>	a one (1) dimensional numeric or integer vector of dependent data, each element $i$ corresponding to each observation (row) $i$ of <code>txdat</code> . Defaults to the training data used to compute the bandwidth object.
<code>tzdat</code>	a $q$ -variate data frame of explanatory data (training data), corresponding to $Z$ in the model equation, whose relationship to the dependent variable is unspecified (nonparametric). Defaults to the training data used to compute the bandwidth object.
<code>exdat</code>	a $p$ -variate data frame of points on which the regression will be estimated (evaluation data). By default, evaluation takes place on the data provided by <code>txdat</code> .
<code>eydat</code>	a one (1) dimensional numeric or integer vector of the true values of the dependent variable. Optional, and used only to calculate the true errors. By default, evaluation takes place on the data provided by <code>tydat</code> .
<code>ezdat</code>	a $q$ -variate data frame of points on which the regression will be estimated (evaluation data). By default, evaluation takes place on the data provided by <code>tzdat</code> .
<code>residuals</code>	a logical value indicating that you want residuals computed and returned in the resulting <code>plregression</code> object. Defaults to <code>FALSE</code> .

## Details

`npplreg` uses a combination of OLS and nonparametric regression to estimate the parameter  $\beta$  in the model  $Y = X\beta + \Theta(Z) + \epsilon$ .

`npplreg` implements a variety of methods for nonparametric regression on multivariate ( $q$ -variate) explanatory data defined over a set of possibly continuous and/or discrete (unordered, ordered) data. The approach is based on Li and Racine (2003) who employ ‘generalized product kernels’ that admit a mix of continuous and discrete data types.

Three classes of kernel estimators for the continuous data types are available: fixed, adaptive nearest-neighbor, and generalized nearest-neighbor. Adaptive nearest-neighbor bandwidths change with each sample realization in the set,  $x_i$ , when estimating the density at the point  $x$ . Generalized nearest-neighbor bandwidths change with the point at which the density is estimated,  $x$ . Fixed bandwidths are constant over the support of  $x$ .

Data contained in the data frame `tzdat` may be a mix of continuous (default), unordered discrete (to be specified in the data frame `tzdat` using `factor`), and ordered discrete (to be specified in the data frame `tzdat` using `ordered`). Data can be entered in an arbitrary order and data types will be detected automatically by the routine (see `np` for details).

A variety of kernels may be specified by the user. Kernels implemented for continuous data types include the second, fourth, sixth, and eighth order Gaussian and Epanechnikov kernels, and the uniform kernel. Unordered discrete data types use a variation on Aitchison and Aitken’s (1976) kernel, while ordered data types use a variation of the Wang and van Ryzin (1981) kernel.

**Value**

npplreg returns a plregression object. The generic accessor functions `coef`, `fitted`, `residuals`, `predict`, and `vcov`, extract (or estimate) coefficients, estimated values, residuals, predictions, and variance-covariance matrices, respectively, from the returned object. Furthermore, the functions `summary` and `plot` support objects of this type. The returned object has the following components:

<code>evalx</code>	evaluation points
<code>evalz</code>	evaluation points
<code>mean</code>	estimation of the regression, or conditional mean, at the evaluation points
<code>xcoef</code>	coefficient(s) corresponding to the components $\beta_i$ in the model
<code>xcoeferr</code>	standard errors of the coefficients
<code>xcoefvcov</code>	covariance matrix of the coefficients
<code>bw</code>	the bandwidths, stored as a plbandwidth object
<code>resid</code>	if <code>residuals = TRUE</code> , in-sample or out-of-sample residuals where appropriate (or possible)
<code>R2</code>	coefficient of determination (Doksum and Samarov (1995))
<code>MSE</code>	mean squared error
<code>MAE</code>	mean absolute error
<code>MAPE</code>	mean absolute percentage error
<code>CORR</code>	absolute value of Pearson's correlation coefficient
<code>SIGN</code>	fraction of observations where fitted and observed values agree in sign

**Usage Issues**

If you are using data of mixed types, then it is advisable to use the `data.frame` function to construct your input data and not `cbind`, since `cbind` will typically not work as intended on mixed data types and will coerce the data to the same type.

---

npplregbw	<i>Partially Linear Kernel Regression Bandwidth Selection with Mixed Data Types</i>
-----------	---

---

## Description

npplregbw computes a bandwidth object for a partially linear kernel regression estimate of a one (1) dimensional dependent variable on  $p + q$ -variate explanatory data, using the model  $Y = X\beta + \Theta(Z) + \epsilon$  given a set of estimation points, training points (consisting of explanatory data and dependent data), and a bandwidth specification, which can be a rbandwidth object, or a bandwidth vector, bandwidth type and kernel type.

## Usage

```

npplregbw(...)

## S3 method for class 'formula'
npplregbw(formula, data, subset, na.action, call, ...)

## S3 method for class 'NULL'
npplregbw(xdat = stop("invoked without data `xdat`"),
          ydat = stop("invoked without data `ydat`"),
          zdat = stop("invoked without data `zdat`"),
          bws,
          ...)

## Default S3 method:
npplregbw(xdat = stop("invoked without data `xdat`"),
          ydat = stop("invoked without data `ydat`"),
          zdat = stop("invoked without data `zdat`"),
          bws,
          ...,
          bandwidth.compute = TRUE,
          nmulti,
          remin,
          itmax,
          ftol,
          tol,
          small)

## S3 method for class 'plbandwidth'
npplregbw(xdat = stop("invoked without data `xdat`"),

```

```

ydat = stop("invoked without data `ydat'"),
zdat = stop("invoked without data `zdat'"),
bws,
nmulti,
...)

```

## Arguments

formula	a symbolic description of variables on which bandwidth selection is to be performed. The details of constructing a formula are described below.
data	an optional data frame, list or environment (or object coercible to a data frame by <a href="#">as.data.frame</a> ) containing the variables in the model. If not found in data, the variables are taken from <code>environment(formula)</code> , typically the environment from which the function is called.
subset	an optional vector specifying a subset of observations to be used in the fitting process.
na.action	a function which indicates what should happen when the data contain NAs. The default is set by the <a href="#">na.action</a> setting of options, and is <a href="#">na.fail</a> if that is unset. The (recommended) default is <a href="#">na.omit</a> .
call	the original function call. This is passed internally by <a href="#">np</a> when a bandwidth search has been implied by a call to another function. It is not recommended that the user set this.
xdat	a $p$ -variate data frame of explanatory data (training data), corresponding to $X$ in the model equation, whose linear relationship with the dependent data $Y$ is posited.
ydat	a one (1) dimensional numeric or integer vector of dependent data, each element $i$ corresponding to each observation (row) $i$ of <code>xdat</code> .
zdat	a $q$ -variate data frame of explanatory data (training data), corresponding to $Z$ in the model equation, whose relationship to the dependent variable is unspecified (nonparametric)
bws	a bandwidth specification. This can be set as a <code>plbandwidth</code> object returned from an invocation of <code>npplregbw</code> , or as a matrix of bandwidths, where each row is a set of bandwidths for $Z$ , with a column for each variable $Z_i$ . In the first row are the bandwidths for the regression of $Y$ on $Z$ . The following rows contain the bandwidths for the regressions of the columns of $X$ on $Z$ . If specified as a matrix, additional arguments will need to be supplied as necessary to specify the bandwidth type, kernel types, and so on.  If left unspecified, <code>npplregbw</code> will search for optimal bandwidths using <a href="#">npregbw</a> in the course of calculations. If specified, <code>npplregbw</code> will use the given bandwidths as the starting point for the numerical search for optimal bandwidths, unless you specify <code>bandwidth.compute = FALSE</code> .
...	additional arguments supplied to specify the regression type, bandwidth type, kernel types, selection methods, and so on. To do this, you may specify any of <code>regtype</code> , <code>bwmethod</code> , <code>bwscaling</code> , <code>bwtype</code> , <code>ckertype</code> , <code>ckerorder</code> , <code>ukertype</code> , <code>okertype</code> , as described in <a href="#">npregbw</a> .

<code>bandwidth.compute</code>	a logical value which specifies whether to do a numerical search for bandwidths or not. If set to FALSE, a <code>plbandwidth</code> object will be returned with bandwidths set to those specified in <code>bws</code> . Defaults to TRUE.
<code>nmulti</code>	integer number of times to restart the process of finding extrema of the cross-validation function from different (random) initial points. Defaults to <code>min(5, ncol(zdat))</code> .
<code>remin</code>	a logical value which when set as TRUE the search routine restarts from located minima for a minor gain in accuracy. Defaults to TRUE
<code>itmax</code>	integer number of iterations before failure in the numerical optimization routine. Defaults to 10000
<code>ftol</code>	tolerance on the value of the cross-validation function evaluated at located minima. Defaults to $1.19 \times 10^{-7}$ (FLT_EPSILON)
<code>tol</code>	tolerance on the position of located minima of the cross-validation function. Defaults to $1.49 \times 10^{-8}$ ( $\sqrt{\text{DBL\_EPSILON}}$ )
<code>small</code>	a small number, at about the precision of the data type used. Defaults to $2.22 \times 10^{-16}$ (DBL_EPSILON)

## Details

`npplregbw` implements a variety of methods for nonparametric regression on multivariate ( $q$ -variate) explanatory data defined over a set of possibly continuous and/or discrete (unordered, ordered) data. The approach is based on Li and Racine (2003), who employ ‘generalized product kernels’ that admit a mix of continuous and discrete data types.

Three classes of kernel estimators for the continuous data types are available: fixed, adaptive nearest-neighbor, and generalized nearest-neighbor. Adaptive nearest-neighbor bandwidths change with each sample realization in the set,  $x_i$ , when estimating the density at the point  $x$ . Generalized nearest-neighbor bandwidths change with the point at which the density is estimated,  $x$ . Fixed bandwidths are constant over the support of  $x$ .

`npplregbw` may be invoked *either* with a formula-like symbolic description of variables on which bandwidth selection is to be performed *or* through a simpler interface whereby data is passed directly to the function via the `xdat`, `ydat`, and `zdat` parameters. Use of these two interfaces is **mutually exclusive**.

Data contained in the data frame `zdat` may be a mix of continuous (default), unordered discrete (to be specified in the data frame `zdat` using [factor](#)), and ordered discrete (to be specified in the data frame `zdat` using [ordered](#)). Data can be entered in an arbitrary order and data types will be detected automatically by the routine (see [np](#) for details).

Data for which bandwidths are to be estimated may be specified symbolically. A typical description has the form dependent data ~ parametric explanatory data | nonparametric explanatory data, where dependent data is a univariate response, and parametric explanatory data and nonparametric explanatory data are both series of variables specified by name, separated by the separation character ‘+’. For example, `y1 ~ x1 + x2 | z1` specifies that the bandwidth object for the partially linear model with response `y1`, linear parametric regressors `x1` and `x2`, and nonparametric regressor `z1` is to be estimated. See below for further examples.

A variety of kernels may be specified by the user. Kernels implemented for continuous data types include the second, fourth, sixth, and eighth order Gaussian and Epanechnikov kernels, and the uniform kernel. Unordered discrete data types use a variation on Aitchison and Aitken’s (1976) kernel, while ordered data types use a variation of the Wang and van Ryzin (1981) kernel.

## Value

if `bwtype` is set to `fixed`, an object containing bandwidths (or scale factors if `bwscaling = TRUE`) is returned. If it is set to `generalized_nn` or `adaptive_nn`, then instead the  $k$ th nearest neighbors are returned for the continuous variables while the discrete kernel bandwidths are returned for the discrete variables. Bandwidths are stored in a list under the component name `bw`. Each element is an `rbandwidth` object. The first element of the list corresponds to the regression of  $Y$  on  $Z$ . Each subsequent element is the bandwidth object corresponding to the regression of the  $i$ th column of  $X$  on  $Z$ . See examples for more information.

## Usage Issues

If you are using data of mixed types, then it is advisable to use the `data.frame` function to construct your input data and not `cbind`, since `cbind` will typically not work as intended on mixed data types and will coerce the data to the same type.

Caution: multivariate data-driven bandwidth selection methods are, by their nature, *computationally intensive*. Virtually all methods require dropping the  $i$ th observation from the data set, computing an object, repeating this for all observations in the sample, then averaging each of these leave-one-out estimates for a *given* value of the bandwidth vector, and only then repeating this a large number of times in order to conduct multivariate numerical minimization/maximization. Furthermore, due to the potential for local minima/maxima, *restarting this procedure a large number of times may often be necessary*. This can be frustrating for users possessing large datasets. For exploratory purposes, you may wish to override the default search tolerances, say, setting `ftol=.01` and `tol=.01` and conduct multistarting (the default is to restart `min(5, ncol(zdat))` times) as is done for a number of examples. Once the procedure terminates, you can restart search with default tolerances using those bandwidths obtained from the less rigorous search (i.e., set `bws=bw` on subsequent calls to this routine where `bw` is the initial bandwidth object). A version of this package using the `Rmpi` wrapper is under development that allows one to deploy this software in a clustered computing environment to facilitate computation involving large datasets.

npqcmstest	<i>Kernel Consistent Quantile Regression Model Specification Test with Mixed Data Types</i>
------------	---

---

## Description

npqcmstest implements a consistent test for correct specification of parametric quantile regression models (linear or nonlinear) as described in Racine (2006) which extends the work of Zheng (1998).

## Usage

```
npqcmstest(formula,
            data = NULL,
            subset,
            xdat,
            ydat,
            model = stop(paste(sQuote("model"), " has not been provided")),
            tau = 0.5,
            distribution = c("bootstrap", "asymptotic"),
            bwydat = c("y", "varepsilon"),
            boot.method = c("iid", "wild", "wild-rademacher"),
            boot.num = 399,
            pivot = TRUE,
            density.weighted = TRUE,
            random.seed = 42,
            ...)
```

## Arguments

formula	a symbolic description of variables on which the test is to be performed. The details of constructing a formula are described below.
---------	--

<code>data</code>	an optional data frame, list or environment (or object coercible to a data frame by <a href="#">as.data.frame</a> ) containing the variables in the model. If not found in <code>data</code> , the variables are taken from <code>environment(formula)</code> , typically the environment from which the function is called.
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>model</code>	a model object obtained from a call to <a href="#">rq</a> . Important: the call to <a href="#">rq</a> must have the argument <code>model=TRUE</code> or <code>npqcmstest</code> will not work.
<code>xdat</code>	a $p$ -variate data frame of explanatory data (training data) used to calculate the quantile regression estimators.
<code>ydat</code>	a one (1) dimensional numeric or integer vector of dependent data, each element $i$ corresponding to each observation (row) $i$ of <code>xdat</code> .
<code>tau</code>	a numeric value specifying the $\tau$ th quantile is desired
<code>distribution</code>	a character string used to specify the method of estimating the distribution of the statistic to be calculated. <code>bootstrap</code> will conduct bootstrapping. <code>asymptotic</code> will use the normal distribution. Defaults to <code>bootstrap</code> .
<code>bwydat</code>	a character string used to specify the left hand side variable used in bandwidth selection. <code>"varepsilon"</code> uses $1 - \tau$ , $-\tau$ for <code>ydat</code> while <code>"y"</code> will use $y$ . Defaults to <code>"y"</code> .
<code>boot.method</code>	a character string used to specify the bootstrap method. <code>iid</code> will generate independent identically distributed draws. <code>wild</code> will use a wild bootstrap. <code>wild-rademacher</code> will use a wild bootstrap with Rademacher variables. Defaults to <code>iid</code> .
<code>boot.num</code>	an integer value specifying the number of bootstrap replications to use. Defaults to 399.
<code>pivot</code>	a logical value specifying whether the statistic should be normalised such that it approaches $N(0, 1)$ in distribution. Defaults to <code>TRUE</code> .
<code>density.weighted</code>	a logical value specifying whether the statistic should be weighted by the density of <code>xdat</code> . Defaults to <code>TRUE</code> .
<code>random.seed</code>	an integer used to seed R's random number generator. This is to ensure replicability. Defaults to 42.
<code>...</code>	additional arguments supplied to control bandwidth selection on the residuals. One can specify the bandwidth type, kernel types, and so on. To do this, you may specify any of <code>bwscaling</code> , <code>bwtype</code> , <code>ckertype</code> , <code>ckerorder</code> , <code>ukertype</code> , <code>okertype</code> , as described in <a href="#">npregbw</a> . This is necessary if you specify <code>bws</code> as a $p$ -vector and not a bandwidth object, and you do not desire the default behaviours.

## Value

`npqcmstest` returns an object of type `cmstest` with the following components. Components will contain information related to  $J_n$  or  $I_n$  depending on the value of `pivot`:

<code>Jn</code>	the statistic $J_n$
<code>In</code>	the statistic $I_n$
<code>Omega.hat</code>	as described in Racine, J.S. (2006).

q.*	the various quantiles of the statistic Jn (or In if pivot=FALSE) are in components q.90, q.95, q.99 (one-sided 1%, 5%, 10% critical values)
P	the P-value of the statistic
Jn.bootstrap	if pivot=TRUE contains the bootstrap replications of Jn
In.bootstrap	if pivot=FALSE contains the bootstrap replications of In

[summary](#) supports object of type cmstest.

### Usage Issues

If you are using data of mixed types, then it is advisable to use the [data.frame](#) function to construct your input data and not [cbind](#), since [cbind](#) will typically not work as intended on mixed data types and will coerce the data to the same type.

npqreg

---

*Kernel Quantile Regression with Mixed Data Types*

---

## Description

npqreg computes a kernel quantile regression estimate of a one (1) dimensional dependent variable on  $p$ -variate explanatory data, given a set of evaluation points, training points (consisting of explanatory data and dependent data), and a bandwidth specification using the methods of Li and Racine (2008) and Li, Lin and Racine (2013). A bandwidth specification can be a `condbandwidth` object, or a bandwidth vector, bandwidth type and kernel type.

## Usage

```
npqreg(bws, ...)
```

```

## S3 method for class 'formula'
npqreg(bws, data = NULL, newdata = NULL, ...)

## S3 method for class 'call'
npqreg(bws, ...)

## S3 method for class 'condbandwidth'
npqreg(bws,
      txdat = stop("training data 'txdat' missing"),
      tydat = stop("training data 'tydat' missing"),

      dfc.dir = 3,
      cfac.dir = 2.5*(3.0-sqrt(5)),
      initc.dir = 1.0,
      lbd.dir = 0.1,
      hbd.dir = 1,
      dfac.dir = 0.25*(3.0-sqrt(5)),
      initd.dir = 1.0,
      ...)

## Default S3 method:
npqreg(bws, txdat, tydat, ...)

```

## Arguments

<code>bws</code>	a bandwidth specification. This can be set as a <code>condbandwidth</code> object returned from an invocation of <code>npcdistbw</code> , or as a vector of bandwidths, with each element $i$ corresponding to the bandwidth for column $i$ in <code>txdat</code> . If specified as a vector, then additional arguments will need to be supplied as necessary to specify the bandwidth type, kernel types, and so on.
<code>tau</code>	a numeric value specifying the $\tau$ th quantile is desired. Defaults to 0.5.
<code>...</code>	additional arguments supplied to specify the regression type, bandwidth type, kernel types, training data, and so on. To do this, you may specify any of <code>bwmethod</code> , <code>bwscaling</code> , <code>bwtype</code> , <code>cxkertype</code> , <code>cxkerorder</code> , <code>cykertype</code> , <code>cykerorder</code> , <code>uxkertype</code> , <code>uykertype</code> , <code>oxkertype</code> , <code>oykertype</code> , as described in <code>npcdistbw</code> .
<code>data</code>	an optional data frame, list or environment (or object coercible to a data frame by <code>as.data.frame</code> ) containing the variables in the model. If not found in <code>data</code> , the variables are taken from <code>environment(bws)</code> , typically the environment from which <code>npcdistbw</code> was called.

<code>newdata</code>	An optional data frame in which to look for evaluation data. If omitted, the training data are used.
<code>txdat</code>	a $p$ -variate data frame of explanatory data (training data) used to calculate the regression estimators. Defaults to the training data used to compute the bandwidth object.
<code>tydat</code>	a one (1) dimensional numeric or integer vector of dependent data, each element $i$ corresponding to each observation (row) $i$ of <code>txdat</code> . Defaults to the training data used to compute the bandwidth object.
<code>exdat</code>	a $p$ -variate data frame of points on which the regression will be estimated (evaluation data). By default, evaluation takes place on the data provided by <code>txdat</code> .
<code>gradients</code>	[currently not supported] a logical value indicating that you want gradients computed and returned in the resulting <code>npregression</code> object. Defaults to <code>FALSE</code> .
<code>itmax</code>	integer number of iterations before failure in the numerical optimization routine. Defaults to 10000.
<code>ftol</code>	fractional tolerance on the value of the cross-validation function evaluated at located minima (of order the machine precision or perhaps slightly larger so as not to be diddled by roundoff). Defaults to $1.490116e-07$ ( $1.0e+01 * \sqrt{.Machine\$double.eps}$ ).
<code>tol</code>	tolerance on the position of located minima of the cross-validation function (tol should generally be no smaller than the square root of your machine's floating point precision). Defaults to $1.490116e-04$ ( $1.0e+04 * \sqrt{.Machine\$double.eps}$ ).
<code>small</code>	a small number used to bracket a minimum (it is hopeless to ask for a bracketing interval of width less than $\sqrt{\epsilon}$ times its central value, a fractional width of only about $10^{-4}$ (single precision) or $3 \times 10^{-8}$ (double precision)). Defaults to $small = 1.490116e-05$ ( $1.0e+03 * \sqrt{.Machine\$double.eps}$ ).
<code>lbc.dir, dfc.dir, cfac.dir, initc.dir</code>	lower bound, chi-square degrees of freedom, stretch factor, and initial non-random values for direction set search for Powell's algorithm for numeric variables. See Details
<code>lbd.dir, hbd.dir, dfac.dir, initd.dir</code>	lower bound, upper bound, stretch factor, and initial non-random values for direction set search for Powell's algorithm for categorical variables. See Details

## Details

The optimizer invoked for search is Powell's conjugate direction method which requires the setting of (non-random) initial values and search directions for bandwidths, and, when restarting, random values for successive invocations. Bandwidths for numeric variables are scaled by robust measures of spread, the sample size, and the number of numeric variables where appropriate. Two sets of parameters for bandwidths for numeric can be modified, those for initial values for the parameters themselves, and those for the directions taken (Powell's algorithm does not involve explicit computation of the function's gradient). The default values are set by considering search performance for a variety of difficult test cases and simulated cases. We highly recommend restarting search a large number of times to avoid the presence of local minima (achieved by modifying `nmulti`). Further refinement for difficult cases can be achieved by modifying these sets of parameters. However, these parameters are intended more for the authors of the package to enable 'tuning' for various methods rather than for the user themselves.

**Value**

npqreg returns a npqregression object. The generic functions `fitted` (or `quantile`), `se`, `predict` (when using `predict` you must add the argument `tau=` to generate predictions other than the median), and `gradients`, extract (or generate) estimated values, asymptotic standard errors on estimates, predictions, and gradients, respectively, from the returned object. Furthermore, the functions `summary` and `plot` support objects of this type. The returned object has the following components:

<code>eval</code>	evaluation points
<code>quantile</code>	estimation of the quantile regression function (conditional quantile) at the evaluation points
<code>quanterr</code>	standard errors of the quantile regression estimates
<code>quantgrad</code>	gradients at each evaluation point
<code>tau</code>	the $\tau$ th quantile computed

**Usage Issues**

If you are using data of mixed types, then it is advisable to use the `data.frame` function to construct your input data and not `cbind`, since `cbind` will typically not work as intended on mixed data types and will coerce the data to the same type.

```

---

npquantile

---

*Kernel Univariate Quantile Estimation*

---

## Description

npquantile computes smooth quantiles from a univariate unconditional kernel cumulative distribution estimate given data and, optionally, a bandwidth specification i.e. a dbandwidth object using the bandwidth selection method of Li, Li and Racine (2017).

## Usage

```

npquantile(x = NULL,
           tau = c(0.01, 0.05, 0.25, 0.50, 0.75, 0.95, 0.99),
           num.eval = 10000,
           bws = NULL,
           f = 1,
           ...)

```

## Arguments

<code>x</code>	a univariate vector of type <code>numeric</code> containing sample realizations (training data) used to estimate the cumulative distribution (must be the same training data used to compute the bandwidth object <code>bws</code> passed in).
<code>tau</code>	an optional vector containing the probabilities for quantile(s) to be estimated (must contain numbers in $[0, 1]$ ). Defaults to <code>c(0.01, 0.05, 0.25, 0.50, 0.75, 0.95, 0.99)</code> .
<code>num.eval</code>	an optional integer specifying the length of the grid on which the quasi-inverse is computed. Defaults to 10000.
<code>bws</code>	an optional <code>dbandwidth</code> specification (if already computed avoid unnecessary computation inside <code>npquantile</code> ). This must be set as a <code>dbandwidth</code> object returned from an invocation of <code>npudistbw</code> . If not provided <code>npudistbw</code> is invoked with optional arguments passed via <code>...</code>
<code>f</code>	an optional argument fed to <code>extendrange</code> . Defaults to 1. See <code>?extendrange</code> for details.
<code>...</code>	additional arguments supplied to specify the bandwidth type, kernel types, bandwidth selection methods, and so on. See <code>?npudistbw</code> for details.

## Details

Typical usage is

```
x <- rchisq(100,df=10)
npquantile(x)
```

The quantile function  $q_\tau$  is defined to be the left-continuous inverse of the distribution function  $F(x)$ , i.e.  $q_\tau = \inf\{x : F(x) \geq \tau\}$ .

A traditional estimator of  $q_\tau$  is the  $\tau$ th sample quantile. However, these estimates suffer from lack of efficiency arising from variability of individual order statistics; see Sheather and Marron (1990) and Hyndman and Fan (1996) for methods that interpolate/smooth the order statistics, each of which discussed in the latter can be invoked through `quantile` via `type=j`,  $j=1, \dots, 9$ .

The function `npquantile` implements a method for estimating smooth quantiles based on the quasi-inverse of a `npudist` object where  $F(x)$  is replaced with its kernel estimator and bandwidth selection is that appropriate for such objects; see Definition 2.3.6, page 21, Nelsen 2006 for a definition of the quasi-inverse of  $F(x)$ .

For construction of the quasi-inverse we create a grid of evaluation points based on the function `extendrange` along with the sample quantiles themselves computed from invocation of `quantile`. The coarseness of the grid defined by `extendrange` (which has been passed the option `f=1`) is controlled by `num.eval`.

Note that for any value of  $\tau$  less/greater than the smallest/largest value of  $F(x)$  computed for the evaluation data (i.e. that outlined in the paragraph above), the quantile returned for such values is that associated with the smallest/largest value of  $F(x)$ , respectively.

## Value

`npquantile` returns a vector of quantiles corresponding to `tau`.

## Usage Issues

Cross-validated bandwidth selection is used by default (`npudistbw`). For large datasets this can be computationally demanding. In such cases one might instead consider a rule-of-thumb bandwidth (`bwmethod="normal-reference"`) or, alternatively, use kd-trees (`options(np.tree=TRUE)` along with a bounded kernel (`ckertype="epanechnikov"`)), both of which will reduce the computational burden appreciably.

---

npreg

---

*Kernel Regression with Mixed Data Types*

---

## Description

npreg computes a kernel regression estimate of a one (1) dimensional dependent variable on  $p$ -variate explanatory data, given a set of evaluation points, training points (consisting of explanatory data and dependent data), and a bandwidth specification using the method of Racine and Li (2004) and Li and Racine (2004). A bandwidth specification can be a rbandwidth object, or a bandwidth vector, bandwidth type and kernel type.

## Usage

```
npreg(bws, ...)

## S3 method for class 'formula'
npreg(bws, data = NULL, newdata = NULL, y.eval =
FALSE, ...)

## S3 method for class 'call'
npreg(bws, ...)

## Default S3 method:
npreg(bws, txdat, tydat, ...)

## S3 method for class 'rbandwidth'
npreg(bws,
      txdat = stop("training data 'txdat' missing"),
      tydat = stop("training data 'tydat' missing"),
      exdat,
      eydat,
      gradients = FALSE,
      residuals = FALSE,
      ...)
```

## Arguments

bws	a bandwidth specification. This can be set as a rbandwidth object returned from an invocation of <a href="#">npregbw</a> , or as a vector of bandwidths, with each element $i$ corresponding to the bandwidth for column $i$ in txdat. If specified as a vector, then additional arguments will need to be supplied as necessary to specify the bandwidth type, kernel types, and so on.
-----	--

...	additional arguments supplied to specify the regression type, bandwidth type, kernel types, training data, and so on, detailed below.
data	an optional data frame, list or environment (or object coercible to a data frame by <a href="#">as.data.frame</a> ) containing the variables in the model. If not found in data, the variables are taken from <code>environment(bws)</code> , typically the environment from which <code>npregbw</code> was called.
newdata	An optional data frame in which to look for evaluation data. If omitted, the training data are used.
y.eval	If newdata contains dependent data and <code>y.eval = TRUE</code> , <code>np</code> will compute goodness of fit statistics on these data and return them. Defaults to FALSE.
txdat	a $p$ -variate data frame of explanatory data (training data) used to calculate the regression estimators. Defaults to the training data used to compute the bandwidth object.
tydat	a one (1) dimensional numeric or integer vector of dependent data, each element $i$ corresponding to each observation (row) $i$ of txdat. Defaults to the training data used to compute the bandwidth object.
exdat	a $p$ -variate data frame of points on which the regression will be estimated (evaluation data). By default, evaluation takes place on the data provided by txdat.
eydat	a one (1) dimensional numeric or integer vector of the true values of the dependent variable. Optional, and used only to calculate the true errors.
gradients	a logical value indicating that you want gradients computed and returned in the resulting <code>npregression</code> object. Defaults to FALSE.
residuals	a logical value indicating that you want residuals computed and returned in the resulting <code>npregression</code> object. Defaults to FALSE.

## Details

Typical usages are (see below for a complete list of options and also the examples at the end of this help file)

Usage 1: first compute the bandwidth object via `npregbw` and then compute the conditional mean:

```
bw <- npregbw(y~x)
ghat <- npreg(bw)
```

Usage 2: alternatively, compute the bandwidth object indirectly:

```
ghat <- npreg(y~x)
```

Usage 3: modify the default kernel and order:

```
ghat <- npreg(y~x, ckertype="epanechnikov", ckerorder=4)
```

Usage 4: use the data frame interface rather than the formula interface:

```
ghat <- npreg(tydat=y, txdat=x, ckertype="epanechnikov", ckerorder=4)
```

npreg implements a variety of methods for regression on multivariate ( $p$ -variate) data, the types of which are possibly continuous and/or discrete (unordered, ordered). The approach is based on Li and Racine (2003) who employ ‘generalized product kernels’ that admit a mix of continuous and discrete data types.

Three classes of kernel estimators for the continuous data types are available: fixed, adaptive nearest-neighbor, and generalized nearest-neighbor. Adaptive nearest-neighbor bandwidths change with each sample realization in the set,  $x_i$ , when estimating the density at the point  $x$ . Generalized nearest-neighbor bandwidths change with the point at which the density is estimated,  $x$ . Fixed bandwidths are constant over the support of  $x$ .

Data contained in the data frame `txdat` may be a mix of continuous (default), unordered discrete (to be specified in the data frame `txdat` using `factor`), and ordered discrete (to be specified in the data frame `txdat` using `ordered`). Data can be entered in an arbitrary order and data types will be detected automatically by the routine (see `np` for details).

A variety of kernels may be specified by the user. Kernels implemented for continuous data types include the second, fourth, sixth, and eighth order Gaussian and Epanechnikov kernels, and the uniform kernel. Unordered discrete data types use a variation on Aitchison and Aitken’s (1976) kernel, while ordered data types use a variation of the Wang and van Ryzin (1981) kernel.

The use of compactly supported kernels or the occurrence of small bandwidths can lead to numerical problems for the local linear estimator when computing the locally weighted least squares solution. To overcome this problem we rely on a form of ‘ridging’ proposed by Cheng, Hall, and Titterington (1997), modified so that we solve the problem pointwise rather than globally (i.e. only when it is needed).

## Value

npreg returns a `npregression` object. The generic functions `fitted`, `residuals`, `se`, `predict`, and `gradients`, extract (or generate) estimated values, residuals, asymptotic standard errors on estimates, predictions, and gradients, respectively, from the returned object. Furthermore, the functions `summary` and `plot` support objects of this type. The returned object has the following components:

<code>eval</code>	evaluation points
<code>mean</code>	estimates of the regression function (conditional mean) at the evaluation points
<code>merr</code>	standard errors of the regression function estimates
<code>grad</code>	estimates of the gradients at each evaluation point
<code>gerr</code>	standard errors of the gradient estimates
<code>resid</code>	if <code>residuals = TRUE</code> , in-sample or out-of-sample residuals where appropriate (or possible)
<code>R2</code>	coefficient of determination (Doksum and Samarov (1995))
<code>MSE</code>	mean squared error
<code>MAE</code>	mean absolute error
<code>MAPE</code>	mean absolute percentage error
<code>CORR</code>	absolute value of Pearson’s correlation coefficient
<code>SIGN</code>	fraction of observations where fitted and observed values agree in sign

## Usage Issues

If you are using data of mixed types, then it is advisable to use the `data.frame` function to construct your input data and not `cbind`, since `cbind` will typically not work as intended on mixed data types and will coerce the data to the same type.

## Arguments

formula	a symbolic description of variables on which bandwidth selection is to be performed. The details of constructing a formula are described below.
data	an optional data frame, list or environment (or object coercible to a data frame by <code>as.data.frame</code> ) containing the variables in the model. If not found in data, the variables are taken from <code>environment(formula)</code> , typically the environment from which the function is called.
subset	an optional vector specifying a subset of observations to be used in the fitting process.
na.action	a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of options, and is <code>na.fail</code> if that is unset. The (recommended) default is <code>na.omit</code> .
call	the original function call. This is passed internally by <code>np</code> when a bandwidth search has been implied by a call to another function. It is not recommended that the user set this.
xdat	a $p$ -variate data frame of regressors on which bandwidth selection will be performed. The data types may be continuous, discrete (unordered and ordered factors), or some combination thereof.
ydat	a one (1) dimensional numeric or integer vector of dependent data, each element $i$ corresponding to each observation (row) $i$ of <code>xdat</code> .
bws	a bandwidth specification. This can be set as a <code>rbandwidth</code> object returned from a previous invocation, or as a vector of bandwidths, with each element $i$ corresponding to the bandwidth for column $i$ in <code>xdat</code> . In either case, the bandwidth supplied will serve as a starting point in the numerical search for optimal bandwidths. If specified as a vector, then additional arguments will need to be supplied as necessary to specify the bandwidth type, kernel types, selection methods, and so on. This can be left unset.
...	additional arguments supplied to specify the bandwidth type, kernel types, selection methods, and so on, detailed below.
regtype	a character string specifying which type of kernel regression estimator to use. <code>lc</code> specifies a local-constant estimator (Nadaraya-Watson) and <code>ll</code> specifies a local-linear estimator. Defaults to <code>lc</code> .
bwmethod	which method to use to select bandwidths. <code>cv.aic</code> specifies expected Kullback-Leibler cross-validation (Hurvich, Simonoff, and Tsai (1998)), and <code>cv.ls</code> specifies least-squares cross-validation. Defaults to <code>cv.ls</code> .
bwscaling	a logical value that when set to <code>TRUE</code> the supplied bandwidths are interpreted as ‘scale factors’ ( $c_j$ ), otherwise when the value is <code>FALSE</code> they are interpreted as ‘raw bandwidths’ ( $h_j$ for continuous data types, $\lambda_j$ for discrete data types). For continuous data types, $c_j$ and $h_j$ are related by the formula $h_j = c_j \sigma_j n^{-1/(2P+1)}$ , where $\sigma_j$ is an adaptive measure of spread of continuous variable $j$ defined as

	<p><math>\min(\text{standard deviation}, \text{mean absolute deviation}/1.4826, \text{interquartile range}/1.349)</math>, <math>n</math> the number of observations, <math>P</math> the order of the kernel, and <math>l</math> the number of continuous variables. For discrete data types, <math>c_j</math> and <math>h_j</math> are related by the formula <math>h_j = c_j n^{-2/(2P+l)}</math>, where here <math>j</math> denotes discrete variable <math>j</math>. Defaults to FALSE.</p>
bwtype	<p>character string used for the continuous variable bandwidth type, specifying the type of bandwidth to compute and return in the bandwidth object. Defaults to fixed. Option summary:  fixed: compute fixed bandwidths  generalized_nn: compute generalized nearest neighbors  adaptive_nn: compute adaptive nearest neighbors</p>
bandwidth.compute	<p>a logical value which specifies whether to do a numerical search for bandwidths or not. If set to FALSE, a rbandwidth object will be returned with bandwidths set to those specified in bws. Defaults to TRUE.</p>
ckertype	<p>character string used to specify the continuous kernel type. Can be set as gaussian, epanechnikov, or uniform. Defaults to gaussian.</p>
ckerorder	<p>numeric value specifying kernel order (one of (2, 4, 6, 8)). Kernel order specified along with a uniform continuous kernel type will be ignored. Defaults to 2.</p>
ukertype	<p>character string used to specify the unordered categorical kernel type. Can be set as aitchisonaitken or liracine. Defaults to aitchisonaitken.</p>
okertype	<p>character string used to specify the ordered categorical kernel type. Can be set as wangvanryzin or liracine. Defaults to liracine.</p>
nmulti	<p>integer number of times to restart the process of finding extrema of the cross-validation function from different (random) initial points. Defaults to <math>\min(5, \text{ncol}(\text{xdat}))</math>.</p>
remin	<p>a logical value which when set as TRUE the search routine restarts from located minima for a minor gain in accuracy. Defaults to TRUE.</p>
itmax	<p>integer number of iterations before failure in the numerical optimization routine. Defaults to 10000.</p>
ftol	<p>fractional tolerance on the value of the cross-validation function evaluated at located minima (of order the machine precision or perhaps slightly larger so as not to be diddled by roundoff). Defaults to <math>1.490116\text{e-}07</math> (<math>1.0\text{e+}01 * \text{sqrt}(\text{.Machine\\$double.eps})</math>).</p>
tol	<p>tolerance on the position of located minima of the cross-validation function (tol should generally be no smaller than the square root of your machine's floating point precision). Defaults to <math>1.490116\text{e-}04</math> (<math>1.0\text{e+}04 * \text{sqrt}(\text{.Machine\\$double.eps})</math>).</p>
small	<p>a small number used to bracket a minimum (it is hopeless to ask for a bracketing interval of width less than <math>\text{sqrt}(\text{epsilon})</math> times its central value, a fractional width of only about <math>10^{-4}</math> (single precision) or <math>3 \times 10^{-8}</math> (double precision)). Defaults to <math>\text{small} = 1.490116\text{e-}05</math> (<math>1.0\text{e+}03 * \text{sqrt}(\text{.Machine\\$double.eps})</math>).</p>
lbc.dir, dfc.dir, cfac.dir, initc.dir	<p>lower bound, chi-square degrees of freedom, stretch factor, and initial non-random values for direction set search for Powell's algorithm for numeric variables. See Details</p>
lbd.dir, hbd.dir, dfac.dir, initd.dir	<p>lower bound, upper bound, stretch factor, and initial non-random values for direction set search for Powell's algorithm for categorical variables. See Details</p>

lbc.init, hbc.init, cfac.init  
 lower bound, upper bound, and non-random initial values for scale factors for numeric variables for Powell's algorithm. See Details

lbd.init, hbd.init, dfac.init  
 lower bound, upper bound, and non-random initial values for scale factors for categorical variables for Powell's algorithm. See Details

scale.init.categorical.sample  
 a logical value that when set to TRUE scales lbd.dir, hbd.dir, dfac.dir, and initd.dir by  $n^{-2/(2P+l)}$ ,  $n$  the number of observations,  $P$  the order of the kernel, and  $l$  the number of numeric variables. See Details

## Details

npregbw implements a variety of methods for choosing bandwidths for multivariate ( $p$ -variate) regression data defined over a set of possibly continuous and/or discrete (unordered, ordered) data. The approach is based on Li and Racine (2003) who employ 'generalized product kernels' that admit a mix of continuous and discrete data types.

The cross-validation methods employ multivariate numerical search algorithms (direction set (Powell's) methods in multidimensions).

Bandwidths can (and will) differ for each variable which is, of course, desirable.

Three classes of kernel estimators for the continuous data types are available: fixed, adaptive nearest-neighbor, and generalized nearest-neighbor. Adaptive nearest-neighbor bandwidths change with each sample realization in the set,  $x_i$ , when estimating the density at the point  $x$ . Generalized nearest-neighbor bandwidths change with the point at which the density is estimated,  $x$ . Fixed bandwidths are constant over the support of  $x$ .

npregbw may be invoked *either* with a formula-like symbolic description of variables on which bandwidth selection is to be performed *or* through a simpler interface whereby data is passed directly to the function via the xdat and ydat parameters. Use of these two interfaces is **mutually exclusive**.

Data contained in the data frame xdat may be a mix of continuous (default), unordered discrete (to be specified in the data frame xdat using [factor](#)), and ordered discrete (to be specified in the data frame xdat using [ordered](#)). Data can be entered in an arbitrary order and data types will be detected automatically by the routine (see [np](#) for details).

Data for which bandwidths are to be estimated may be specified symbolically. A typical description has the form dependent data ~ explanatory data, where dependent data is a univariate response, and explanatory data is a series of variables specified by name, separated by the separation character '+'. For example, `y1 ~ x1 + x2` specifies that the bandwidths for the regression of response y1 and nonparametric regressors x1 and x2 are to be estimated. See below for further examples.

A variety of kernels may be specified by the user. Kernels implemented for continuous data types include the second, fourth, sixth, and eighth order Gaussian and Epanechnikov kernels, and the uniform kernel. Unordered discrete data types use a variation on Aitchison and Aitken's (1976) kernel, while ordered data types use a variation of the Wang and van Ryzin (1981) kernel.

The use of compactly supported kernels or the occurrence of small bandwidths during cross-validation can lead to numerical problems for the local linear estimator when computing the locally weighted least squares solution. To overcome this problem we rely on a form of 'ridging' proposed by Cheng,

Hall, and Titterington (1997), modified so that we solve the problem pointwise rather than globally (i.e. only when it is needed).

The optimizer invoked for search is Powell's conjugate direction method which requires the setting of (non-random) initial values and search directions for bandwidths, and, when restarting, random values for successive invocations. Bandwidths for numeric variables are scaled by robust measures of spread, the sample size, and the number of numeric variables where appropriate. Two sets of parameters for bandwidths for numeric can be modified, those for initial values for the parameters themselves, and those for the directions taken (Powell's algorithm does not involve explicit computation of the function's gradient). The default values are set by considering search performance for a variety of difficult test cases and simulated cases. We highly recommend restarting search a large number of times to avoid the presence of local minima (achieved by modifying `nmulti`). Further refinement for difficult cases can be achieved by modifying these sets of parameters. However, these parameters are intended more for the authors of the package to enable 'tuning' for various methods rather than for the user themselves.

## Value

`npregbw` returns a `rbandwidth` object, with the following components:

<code>bw</code>	bandwidth(s), scale factor(s) or nearest neighbours for the data, <code>xdat</code>
<code>fval</code>	objective function value at minimum

if `bwtype` is set to `fixed`, an object containing bandwidths (or scale factors if `bwscaling` = `TRUE`) is returned. If it is set to `generalized_nn` or `adaptive_nn`, then instead the  $k$ th nearest neighbors are returned for the continuous variables while the discrete kernel bandwidths are returned for the discrete variables. Bandwidths are stored under the component name `bw`, with each element  $i$  corresponding to column  $i$  of input data `xdat`.

The functions `predict`, `summary`, and `plot` support objects of this class.

## Usage Issues

If you are using data of mixed types, then it is advisable to use the `data.frame` function to construct your input data and not `cbind`, since `cbind` will typically not work as intended on mixed data types and will coerce the data to the same type.

Caution: multivariate data-driven bandwidth selection methods are, by their nature, *computationally intensive*. Virtually all methods require dropping the  $i$ th observation from the data set, computing an object, repeating this for all observations in the sample, then averaging each of these leave-one-out estimates for a *given* value of the bandwidth vector, and only then repeating this a large number of times in order to conduct multivariate numerical minimization/maximization. Furthermore, due to the potential for local minima/maxima, *restarting this procedure a large number of times may often be necessary*. This can be frustrating for users possessing large datasets. For exploratory purposes, you may wish to override the default search tolerances, say, setting `ftol=.01` and `tol=.01` and conduct multistarting (the default is to restart `min(5, ncol(xdat))` times) as is done for a number of examples. Once the procedure terminates, you can restart search with default tolerances using those bandwidths obtained from the less rigorous search (i.e., set `bws=bw` on subsequent calls to this routine where `bw` is the initial bandwidth object). A version of this package using the `Rmpi` wrapper is under development that allows one to deploy this software in a clustered computing environment to facilitate computation involving large datasets.

---

npregiv

---

*Nonparametric Instrumental Regression*

---

## Description

npregiv computes nonparametric estimation of an instrumental regression function  $\varphi$  defined by conditional moment restrictions stemming from a structural econometric model:  $E[Y - \varphi(Z, X)|W] = 0$ , and involving endogenous variables  $Y$  and  $Z$  and exogenous variables  $X$  and instruments  $W$ . The function  $\varphi$  is the solution of an ill-posed inverse problem.

When method="Tikhonov", npregiv uses the approach of Darolles, Fan, Florens and Renault (2011) modified for local polynomial kernel regression of any order (Darolles et al use local constant kernel weighting which corresponds to setting  $p=0$ ; see below for details). When method="Landweber-Fridman", npregiv uses the approach of Horowitz (2011) again using local polynomial kernel regression (Horowitz uses B-spline weighting).

```

### Arguments

<code>y</code>	a one (1) dimensional numeric or integer vector of dependent data, each element $i$ corresponding to each observation (row) $i$ of <code>z</code> .
<code>z</code>	a $p$ -variate data frame of endogenous regressors. The data types may be continuous, discrete (unordered and ordered factors), or some combination thereof.
<code>w</code>	a $q$ -variate data frame of instruments. The data types may be continuous, discrete (unordered and ordered factors), or some combination thereof.
<code>x</code>	an $r$ -variate data frame of exogenous regressors. The data types may be continuous, discrete (unordered and ordered factors), or some combination thereof.
<code>zeval</code>	a $p$ -variate data frame of endogenous regressors on which the regression will be estimated (evaluation data). By default, evaluation takes place on the data provided by <code>z</code> .
<code>xeval</code>	an $r$ -variate data frame of exogenous regressors on which the regression will be estimated (evaluation data). By default, evaluation takes place on the data provided by <code>x</code> .
<code>p</code>	the order of the local polynomial regression (defaults to $p=1$ , i.e. local linear).
<code>nmulti</code>	integer number of times to restart the process of finding extrema of the cross-validation function from different (random) initial points.
<code>random.seed</code>	an integer used to seed R's random number generator. This ensures replicability of the numerical search. Defaults to 42.

<code>optim.method</code>	<p>method used by <code>optim</code> for minimization of the objective function. See <code>?optim</code> for references. Defaults to "Nelder-Mead".</p> <p>the default method is an implementation of that of Nelder and Mead (1965), that uses only function values and is robust but relatively slow. It will work reasonably well for non-differentiable functions.</p> <p>method "BFGS" is a quasi-Newton method (also known as a variable metric algorithm), specifically that published simultaneously in 1970 by Broyden, Fletcher, Goldfarb and Shanno. This uses function values and gradients to build up a picture of the surface to be optimized.</p> <p>method "CG" is a conjugate gradients method based on that by Fletcher and Reeves (1964) (but with the option of Polak-Ribiere or Beale-Sorenson updates). Conjugate gradient methods will generally be more fragile than the BFGS method, but as they do not store a matrix they may be successful in much larger optimization problems.</p>
<code>optim.maxattempts</code>	<p>maximum number of attempts taken trying to achieve successful convergence in <code>optim</code>. Defaults to 100.</p>
<code>optim.abstol</code>	<p>the absolute convergence tolerance used by <code>optim</code>. Only useful for non-negative functions, as a tolerance for reaching zero. Defaults to <code>.Machine\$double.eps</code>.</p>
<code>optim.reltol</code>	<p>relative convergence tolerance used by <code>optim</code>. The algorithm stops if it is unable to reduce the value by a factor of <code>'reltol * (abs(val) + reltol)'</code> at a step. Defaults to <code>sqrt(.Machine\$double.eps)</code>, typically about <code>1e-8</code>.</p>
<code>optim.maxit</code>	<p>maximum number of iterations used by <code>optim</code>. Defaults to 500.</p>
<code>alpha</code>	<p>a numeric scalar that, if supplied, is used rather than numerically solving for <code>alpha</code>, when using <code>method="Tikhonov"</code>.</p>
<code>alpha.iter</code>	<p>a numeric scalar that, if supplied, is used for iterated Tikhonov rather than numerically solving for <code>alpha</code>, when using <code>method="Tikhonov"</code>.</p>
<code>alpha.min</code>	<p>minimum of search range for <math>\alpha</math>, the Tikhonov regularization parameter, when using <code>method="Tikhonov"</code>.</p>
<code>alpha.max</code>	<p>maximum of search range for <math>\alpha</math>, the Tikhonov regularization parameter, when using <code>method="Tikhonov"</code>.</p>
<code>alpha.tol</code>	<p>the search tolerance for optimize when solving for <math>\alpha</math>, the Tikhonov regularization parameter, when using <code>method="Tikhonov"</code>.</p>
<code>iterate.Tikhonov</code>	<p>a logical value indicating whether to use iterated Tikhonov (one iteration) or not when using <code>method="Tikhonov"</code>.</p>
<code>iterate.Tikhonov.num</code>	<p>an integer indicating the number of iterations to conduct when using <code>method="Tikhonov"</code>.</p>
<code>iterate.max</code>	<p>an integer indicating the maximum number of iterations permitted before termination occurs when using <code>method="Landweber-Fridman"</code>.</p>
<code>iterate.diff.tol</code>	<p>the search tolerance for the difference in the stopping rule from iteration to iteration when using <code>method="Landweber-Fridman"</code> (disable by setting to zero).</p>
<code>constant</code>	<p>the constant to use when using <code>method="Landweber-Fridman"</code>.</p>

<code>method</code>	the regularization method employed (defaults to "Landweber-Fridman", see Horowitz (2011); see Darolles, Fan, Florens and Renault (2011) for details for "Tikhonov").
<code>penalize.iteration</code>	a logical value indicating whether to penalize the norm by the number of iterations or not (default TRUE)
<code>smooth.residuals</code>	a logical value indicating whether to optimize bandwidths for the regression of $(y - \varphi(z))$ on $w$ (defaults to TRUE) or for the regression of $\varphi(z)$ on $w$ during iteration
<code>start.from</code>	a character string indicating whether to start from $E(Y z)$ (default, "Eyz") or from $E(E(Y z) z)$ (this can be overridden by providing <code>starting.values</code> below)
<code>starting.values</code>	a value indicating whether to commence Landweber-Fridman assuming $\varphi_{-1} = \text{starting.values}$ (proper Landweber-Fridman) or instead begin from $E(y z)$ (defaults to NULL, see details below)
<code>stop.on.increase</code>	a logical value (defaults to TRUE) indicating whether to halt iteration if the stopping criterion (see below) increases over the course of one iteration (i.e. it may be above the iteration tolerance but increased)
<code>return.weights.phi</code>	a logical value (defaults to FALSE) indicating whether to return the weight matrix which when postmultiplied by the response $y$ delivers the instrumental regression
<code>return.weights.phi.deriv.1</code>	a logical value (defaults to FALSE) indicating whether to return the weight matrix which when postmultiplied by the response $y$ delivers the first partial derivative of the instrumental regression with respect to $z$
<code>return.weights.phi.deriv.2</code>	a logical value (defaults to FALSE) indicating whether to return the weight matrix which when postmultiplied by the response $y$ delivers the second partial derivative of the instrumental regression with respect to $z$
<code>bw</code>	an object which, if provided, contains bandwidths and parameters (obtained from a previous invocation of <code>npregiv</code> ) required to re-compute the estimator without having to re-run cross-validation and/or numerical optimization which is particularly costly in this setting (see details below for an illustration of its use)
<code>...</code>	additional arguments supplied to <code>npksum</code> .

## Details

Tikhonov regularization requires computation of weight matrices of dimension  $n \times n$  which can be computationally costly in terms of memory requirements and may be unsuitable for large datasets. Landweber-Fridman will be preferred in such settings as it does not require construction and storage of these weight matrices while it also avoids the need for numerical optimization methods to determine  $\alpha$ .

method="Landweber-Fridman" uses an optimal stopping rule based upon  $\|E(y|w) - E(\varphi_k(z, x)|w)\|^2$ . However, if insufficient training is conducted the estimates can be overly noisy. To best guard against this eventuality set `nmulti` to a larger number than the default `nmulti=1` for `npreg`.

When using method="Landweber-Fridman", iteration will terminate when either the change in the value of  $\|(E(y|w) - E(\varphi_k(z, x)|w))/E(y|w)\|^2$  from iteration to iteration is less than `iterate.diff.tol` or we hit `iterate.max` or  $\|(E(y|w) - E(\varphi_k(z, x)|w))/E(y|w)\|^2$  stops falling in value and starts rising.

The option `bw=` would be useful, say, when bootstrapping is necessary. Note that when passing `bw`, it must be obtained from a previous invocation of `npregiv`. For instance, if `model.iv` was obtained from an invocation of `npregiv` with method="Landweber-Fridman", then the following needs to be fed to the subsequent invocation of `npregiv`:

```
model.iv <- npregiv(\dots)

bw <- NULL
bw$bw.E.y.w <- model.iv$bw.E.y.w
bw$bw.E.y.z <- model.iv$bw.E.y.z
bw$bw.resid.w <- model.iv$bw.resid.w
bw$bw.resid.fitted.w.z <- model.iv$bw.resid.fitted.w.z
bw$norm.index <- model.iv$norm.index

foo <- npregiv(\dots, bw=bw)
```

If, on the other hand `model.iv` was obtained from an invocation of `npregiv` with method="Tikhonov", then the following needs to be fed to the subsequent invocation of `npregiv`:

```
model.iv <- npregiv(\dots)

bw <- NULL
bw$alpha <- model.iv$alpha
bw$alpha.iter <- model.iv$alpha.iter
bw$bw.E.y.w <- model.iv$bw.E.y.w
bw$bw.E.E.y.w.z <- model.iv$bw.E.E.y.w.z
bw$bw.E.phi.w <- model.iv$bw.E.phi.w
bw$bw.E.E.phi.w.z <- model.iv$bw.E.E.phi.w.z

foo <- npregiv(\dots, bw=bw)
```

Or, if `model.iv` was obtained from an invocation of `npregiv` with either method="Landweber-Fridman" or method="Tikhonov", then the following would also work:

```
model.iv <- npregiv(\dots)

foo <- npregiv(\dots,bw=model.iv)
```

When exogenous predictors  $x$  (xeval) are passed, they are appended to both the endogenous predictors  $z$  and the instruments  $w$  as additional columns. If this is not desired, one can manually append the exogenous variables to  $z$  (or  $w$ ) prior to passing  $z$  (or  $w$ ), and then they will only appear among the  $z$  or  $w$  as desired.

### Value

npregiv returns a list with components `phi`, `phi.mat` and either `alpha` when `method="Tikhonov"` or `norm.index`, `norm.stop` and `convergence` when `method="Landweber-Fridman"`, among others.

In addition, if any of `return.weights.*` are invoked ( $*$ =1,2), then `phi.weights` and `phi.deriv.*.weights` return weight matrices for computing the instrumental regression and its partial derivatives. Note that these weights, post multiplied by the response vector  $y$ , will deliver the estimates returned in `phi`, `phi.deriv.1`, and `phi.deriv.2` (the latter only being produced when  $p$  is 2 or greater). When invoked with evaluation data, similar matrices are returned but named `phi.eval.weights` and `phi.deriv.eval.*.weights`. These weights can be used for constrained estimation, among others.

When `method="Landweber-Fridman"` is invoked, bandwidth objects are returned in `bw.E.y.w` (scalar/vector), `bw.E.y.z` (scalar/vector), and `bw.resid.w` (matrix) and `bw.resid.fitted.w.z`, the latter matrices containing bandwidths for each iteration stored as rows. When `method="Tikhonov"` is invoked, bandwidth objects are returned in `bw.E.y.w`, `bw.E.E.y.w.z`, and `bw.E.phi.w` and `bw.E.E.phi.w.z`.

### Note

This function should be considered to be in ‘beta test’ status until further notice.

npregivderiv

*Nonparametric Instrumental Derivatives*

---

## Description

npregivderiv uses the approach of Florens, Racine and Centorrino (2018) to compute the partial derivative of a nonparametric estimation of an instrumental regression function  $\varphi$  defined by conditional moment restrictions stemming from a structural econometric model:  $E[Y - \varphi(Z, X)|W] = 0$ , and involving endogenous variables  $Y$  and  $Z$  and exogenous variables  $X$  and instruments  $W$ . The derivative function  $\varphi'$  is the solution of an ill-posed inverse problem, and is computed using Landweber-Fridman regularization.

## Usage

```
npregivderiv(y,
             z,
             w,
             x = NULL,
             zeval = NULL,
             weval = NULL,
             xeval = NULL,
             random.seed = 42,
             iterate.max = 1000,
             iterate.break = TRUE,
             constant = 0.5,
             start.from = c("Eyz", "EEyz"),
             starting.values = NULL,
             stop.on.increase = TRUE,
             smooth.residuals = TRUE,
             ...)
```

## Arguments

- |   |  |
|---|--|
| y | a one (1) dimensional numeric or integer vector of dependent data, each element $i$ corresponding to each observation (row) $i$ of z.                        |
| z | a $p$ -variate data frame of endogenous regressors. The data types may be continuous, discrete (unordered and ordered factors), or some combination thereof. |
| w | a $q$ -variate data frame of instruments. The data types may be continuous, discrete (unordered and ordered factors), or some combination thereof.           |

<code>x</code>	an $r$ -variate data frame of exogenous regressors. The data types may be continuous, discrete (unordered and ordered factors), or some combination thereof.
<code>zeval</code>	a $p$ -variate data frame of endogenous regressors on which the regression will be estimated (evaluation data). By default, evaluation takes place on the data provided by <code>z</code> .
<code>weval</code>	a $q$ -variate data frame of instruments on which the regression will be estimated (evaluation data). By default, evaluation takes place on the data provided by <code>w</code> .
<code>xeval</code>	an $r$ -variate data frame of exogenous regressors on which the regression will be estimated (evaluation data). By default, evaluation takes place on the data provided by <code>x</code> .
<code>random.seed</code>	an integer used to seed R's random number generator. This ensures replicability of the numerical search. Defaults to 42.
<code>iterate.max</code>	an integer indicating the maximum number of iterations permitted before termination occurs for Landweber-Fridman iteration.
<code>iterate.break</code>	a logical value indicating whether to compute all objects up to <code>iterate.max</code> or to break when a potential optimum arises (useful for inspecting full stopping rule profile up to <code>iterate.max</code> )
<code>constant</code>	the constant to use for Landweber-Fridman iteration.
<code>start.from</code>	a character string indicating whether to start from $E(Y z)$ (default, "Eyz") or from $E(E(Y z) z)$ (this can be overridden by providing <code>starting.values</code> below)
<code>starting.values</code>	a value indicating whether to commence Landweber-Fridman assuming $\varphi'_{-1} = \text{starting.values}$ (proper Landweber-Fridman) or instead begin from $E(y z)$ (defaults to NULL, see details below)
<code>stop.on.increase</code>	a logical value (defaults to TRUE) indicating whether to halt iteration if the stopping criterion (see below) increases over the course of one iteration (i.e. it may be above the iteration tolerance but increased).
<code>smooth.residuals</code>	a logical value (defaults to TRUE) indicating whether to optimize bandwidths for the regression of $y - \varphi(z)$ on $w$ or for the regression of $\varphi(z)$ on $w$ during Landweber-Fridman iteration.
<code>...</code>	additional arguments supplied to <code>npreg</code> and <code>npksum</code> .

## Details

Note that Landweber-Fridman iteration presumes that  $\varphi_{-1} = 0$ , and so for derivative estimation we commence iterating from a model having derivatives all equal to zero. Given this starting point it may require a fairly large number of iterations in order to converge. Other perhaps more reasonable starting values might present themselves. When `start.phi.zero` is set to FALSE iteration will commence instead using derivatives from the conditional mean model  $E(y|z)$ . Should the default iteration terminate quickly or you are concerned about your results, it would be prudent to verify that this alternative starting value produces the same result. Also, check the `norm.stop` vector for any anomalies (such as the error criterion increasing immediately).

Landweber-Fridman iteration uses an optimal stopping rule based upon  $\|E(y|w) - E(\varphi_k(z, x)|w)\|^2$ . However, if insufficient training is conducted the estimates can be overly noisy. To best guard against this eventuality set `nmulti` to a larger number than the default `nmulti=1` for `npreg`.

Iteration will terminate when either the change in the value of  $\|(E(y|w) - E(\varphi_k(z, x)|w))/E(y|w)\|^2$  from iteration to iteration is less than `iterate.diff.tol` or we hit `iterate.max` or  $\|(E(y|w) - E(\varphi_k(z, x)|w))/E(y|w)\|^2$  stops falling in value and starts rising.

### Value

`npregivderiv` returns a list with components `phi.prime`, `phi`, `num.iterations`, `norm.stop` and `convergence`.

### Note

This function currently supports univariate `z` only. This function should be considered to be in ‘beta test’ status until further notice.

npscoef

*Smooth Coefficient Kernel Regression*

---

### Description

npscoef computes a kernel regression estimate of a one (1) dimensional dependent variable on  $p$ -variate explanatory data, using the model  $Y_i = W_i' \gamma(Z_i) + u_i$  where  $W_i' = (1, X_i')$ , given a set of evaluation points, training points (consisting of explanatory data and dependent data), and a bandwidth specification. A bandwidth specification can be a scbandwidth object, or a bandwidth vector, bandwidth type and kernel type.

### Usage

```

npscoef(bws, ...)

## S3 method for class 'formula'
npscoef(bws, data = NULL, newdata = NULL, y.eval =
FALSE, ...)

## S3 method for class 'call'
npscoef(bws, ...)

## Default S3 method:
npscoef(bws, txdat, tydat, tzdat, ...)

## S3 method for class 'scbandwidth'
npscoef(bws,

```

```

txdat = stop("training data 'txdat' missing"),
tydat = stop("training data 'tydat' missing"),
tzdat = NULL,
exdat,
eydat,
ezdat,
residuals = FALSE,
errors = TRUE,
iterate = TRUE,
maxiter = 100,
tol = .Machine$double.eps,
leave.one.out = FALSE,
betas = FALSE,
...)

```

### Arguments

bws	a bandwidth specification. This can be set as a <code>scbandwidth</code> object returned from an invocation of <a href="#">npscoefbw</a> , or as a vector of bandwidths, with each element $i$ corresponding to the bandwidth for column $i$ in <code>tzdat</code> . If specified as a vector additional arguments will need to be supplied as necessary to specify the bandwidth type, kernel types, training data, and so on.
...	additional arguments supplied to specify the regression type, bandwidth type, kernel types, selection methods, and so on. To do this, you may specify any of <code>bwscaling</code> , <code>bwtype</code> , <code>ckertype</code> , <code>ckerorder</code> , as described in <a href="#">npscoefbw</a> .
data	an optional data frame, list or environment (or object coercible to a data frame by <a href="#">as.data.frame</a> ) containing the variables in the model. If not found in data, the variables are taken from <code>environment(bws)</code> , typically the environment from which <a href="#">npscoefbw</a> was called.
newdata	An optional data frame in which to look for evaluation data. If omitted, the training data are used.
y.eval	If <code>newdata</code> contains dependent data and <code>y.eval = TRUE</code> , <a href="#">np</a> will compute goodness of fit statistics on these data and return them. Defaults to <code>FALSE</code> .
txdat	a $p$ -variate data frame of explanatory data (training data), which, by default, populates the columns 2 through $p + 1$ of $W$ in the model equation, and in the absence of <code>zdat</code> , will also correspond to $Z$ from the model equation. Defaults to the training data used to compute the bandwidth object.
tydat	a one (1) dimensional numeric or integer vector of dependent data, each element $i$ corresponding to each observation (row) $i$ of <code>txdat</code> . Defaults to the training data used to compute the bandwidth object.
tzdat	an optionally specified $q$ -variate data frame of explanatory data (training data), which corresponds to $Z$ in the model equation. Defaults to the training data used to compute the bandwidth object.
exdat	a $p$ -variate data frame of points on which the regression will be estimated (evaluation data). By default, evaluation takes place on the data provided by <code>txdat</code> .
eydat	a one (1) dimensional numeric or integer vector of the true values of the dependent variable. Optional, and used only to calculate the true errors.

ezdat	an optionally specified $q$ -variate data frame of points on which the regression will be estimated (evaluation data), which corresponds to $Z$ in the model equation. Defaults to be the same as txdat.
errors	a logical value indicating whether or not asymptotic standard errors should be computed and returned in the resulting smoothcoefficient object. Defaults to TRUE.
residuals	a logical value indicating that you want residuals computed and returned in the resulting smoothcoefficient object. Defaults to FALSE.
iterate	a logical value indicating whether or not backfitted estimates should be iterated for self-consistency. Defaults to TRUE.
maxiter	integer specifying the maximum number of times to iterate the backfitted estimates while attempting to make the backfitted estimates converge to the desired tolerance. Defaults to 100.
tol	desired tolerance on the relative convergence of backfit estimates. Defaults to <code>.Machine\$double.eps</code> .
leave.one.out	a logical value to specify whether or not to compute the leave one out estimates. Will not work if <code>e[xyz]dat</code> is specified. Defaults to FALSE.
betas	a logical value indicating whether or not estimates of the components of $\gamma$ should be returned in the smoothcoefficient object along with the regression estimates. Defaults to FALSE.

## Value

npscoef returns a smoothcoefficient object. The generic functions `fitted`, `residuals`, `coef`, `se`, and `predict`, extract (or generate) estimated values, residuals, coefficients, bootstrapped standard errors on estimates, and predictions, respectively, from the returned object. Furthermore, the functions `summary` and `plot` support objects of this type. The returned object has the following components:

eval	evaluation points
mean	estimation of the regression function (conditional mean) at the evaluation points
merr	if <code>errors = TRUE</code> , standard errors of the regression estimates
beta	if <code>betas = TRUE</code> , estimates of the coefficients $\gamma$ at the evaluation points
resid	if <code>residuals = TRUE</code> , in-sample or out-of-sample residuals where appropriate (or possible)
R2	coefficient of determination (Doksum and Samarov (1995))
MSE	mean squared error
MAE	mean absolute error
MAPE	mean absolute percentage error
CORR	absolute value of Pearson's correlation coefficient
SIGN	fraction of observations where fitted and observed values agree in sign

## Usage Issues

If you are using data of mixed types, then it is advisable to use the `data.frame` function to construct your input data and not `cbind`, since `cbind` will typically not work as intended on mixed data types and will coerce the data to the same type.

Support for backfitted bandwidths is experimental and is limited in functionality. The code does not support asymptotic standard errors or out of sample estimates with backfitting.

npscoefbw

*Smooth Coefficient Kernel Regression Bandwidth Selection*

---

## Description

npscoefbw computes a bandwidth object for a smooth coefficient kernel regression estimate of a one (1) dimensional dependent variable on  $p + q$ -variate explanatory data, using the model  $Y_i = W_i' \gamma(Z_i) + u_i$  where  $W_i' = (1, X_i')$  given training points (consisting of explanatory data and dependent data), and a bandwidth specification, which can be a rbandwidth object, or a bandwidth vector, bandwidth type and kernel type.

### Arguments

formula	a symbolic description of variables on which bandwidth selection is to be performed. The details of constructing a formula are described below.
data	an optional data frame, list or environment (or object coercible to a data frame by <a href="#">as.data.frame</a> ) containing the variables in the model. If not found in data, the variables are taken from <code>environment(formula)</code> , typically the environment from which the function is called.
subset	an optional vector specifying a subset of observations to be used in the fitting process.
na.action	a function which indicates what should happen when the data contain NAs. The

	default is set by the <code>na.action</code> setting of options, and is <code>na.fail</code> if that is unset. The (recommended) default is <code>na.omit</code> .
<code>call</code>	the original function call. This is passed internally by <code>np</code> when a bandwidth search has been implied by a call to another function. It is not recommended that the user set this.
<code>xdat</code>	a $p$ -variate data frame of explanatory data (training data), which, by default, populates the columns 2 through $p + 1$ of $W$ in the model equation, and in the absence of <code>zdat</code> , will also correspond to $Z$ from the model equation.
<code>ydat</code>	a one (1) dimensional numeric or integer vector of dependent data, each element $i$ corresponding to each observation (row) $i$ of <code>xdat</code> .
<code>zdat</code>	an optionally specified $q$ -variate data frame of explanatory data (training data), which corresponds to $Z$ in the model equation. Defaults to be the same as <code>xdat</code> .
<code>bws</code>	a bandwidth specification. This can be set as a <code>scbandwidth</code> object returned from a previous invocation, or as a vector of bandwidths, with each element $i$ corresponding to the bandwidth for column $i$ in <code>xdat</code> . In either case, the bandwidth supplied will serve as a starting point in the numerical search for optimal bandwidths. If specified as a vector, then additional arguments will need to be supplied as necessary to specify the bandwidth type, kernel types, selection methods, and so on. This can be left unset.
<code>...</code>	additional arguments supplied to specify the regression type, bandwidth type, kernel types, selection methods, and so on, detailed below.
<code>bandwidth.compute</code>	a logical value which specifies whether to do a numerical search for bandwidths or not. If set to <code>FALSE</code> , a <code>scbandwidth</code> object will be returned with bandwidths set to those specified in <code>bws</code> . Defaults to <code>TRUE</code> .
<code>bwmethod</code>	which method was used to select bandwidths. <code>cv.ls</code> specifies least-squares cross-validation, which is all that is currently supported. Defaults to <code>cv.ls</code> .
<code>bwscaling</code>	a logical value that when set to <code>TRUE</code> the supplied bandwidths are interpreted as 'scale factors' ( $c_j$ ), otherwise when the value is <code>FALSE</code> they are interpreted as 'raw bandwidths' ( $h_j$ for continuous data types, $\lambda_j$ for discrete data types). For continuous data types, $c_j$ and $h_j$ are related by the formula $h_j = c_j \sigma_j n^{-1/(2P+l)}$ , where $\sigma_j$ is an adaptive measure of spread of continuous variable $j$ defined as $\min(\text{standard deviation, mean absolute deviation, interquartile range}/1.349)$ , $n$ the number of observations, $P$ the order of the kernel, and $l$ the number of continuous variables. For discrete data types, $c_j$ and $h_j$ are related by the formula $h_j = c_j n^{-2/(2P+l)}$ , where here $j$ denotes discrete variable $j$ . Defaults to <code>FALSE</code> .
<code>bwtype</code>	character string used for the continuous variable bandwidth type, specifying the type of bandwidth provided. Defaults to <code>fixed</code> . Option summary: <code>fixed</code> : fixed bandwidths or scale factors <code>generalized_nn</code> : generalized nearest neighbors <code>adaptive_nn</code> : adaptive nearest neighbors
<code>ckertype</code>	character string used to specify the continuous kernel type. Can be set as <code>gaussian</code> , <code>epanechnikov</code> , or <code>uniform</code> . Defaults to <code>gaussian</code> .
<code>ckerorder</code>	numeric value specifying kernel order (one of (2, 4, 6, 8)). Kernel order specified along with a <code>uniform</code> continuous kernel type will be ignored. Defaults to 2.

ukertype	character string used to specify the unordered categorical kernel type. Can be set as aitchisonaitken or liracine. Defaults to aitchisonaitken.
okertype	character string used to specify the ordered categorical kernel type. Can be set as wangvanryzin or liracine. Defaults to liracine.
nmulti	integer number of times to restart the process of finding extrema of the cross-validation function from different (random) initial points. Defaults to $\min(5, \text{ncol}(\text{xdat}))$ .
random.seed	an integer used to seed R's random number generator. This ensures replicability of the numerical search. Defaults to 42.
optim.method	method used by <code>optim</code> for minimization of the objective function. See <code>?optim</code> for references. Defaults to "Nelder-Mead". the default method is an implementation of that of Nelder and Mead (1965), that uses only function values and is robust but relatively slow. It will work reasonably well for non-differentiable functions. method "BFGS" is a quasi-Newton method (also known as a variable metric algorithm), specifically that published simultaneously in 1970 by Broyden, Fletcher, Goldfarb and Shanno. This uses function values and gradients to build up a picture of the surface to be optimized. method "CG" is a conjugate gradients method based on that by Fletcher and Reeves (1964) (but with the option of Polak-Ribiere or Beale-Sorenson updates). Conjugate gradient methods will generally be more fragile than the BFGS method, but as they do not store a matrix they may be successful in much larger optimization problems.
optim.maxattempts	maximum number of attempts taken trying to achieve successful convergence in <code>optim</code> . Defaults to 100.
optim.abstol	the absolute convergence tolerance used by <code>optim</code> . Only useful for non-negative functions, as a tolerance for reaching zero. Defaults to <code>.Machine\$double.eps</code> .
optim.reltol	relative convergence tolerance used by <code>optim</code> . The algorithm stops if it is unable to reduce the value by a factor of $\text{'reltol' * (abs(val) + reltol)}$ at a step. Defaults to $\sqrt{\text{'reltol' * (abs(val) + reltol)}}$ , typically about $1e-8$ .
optim.maxit	maximum number of iterations used by <code>optim</code> . Defaults to 500.
cv.iterate	boolean value specifying whether or not to perform iterative, cross-validated backfitting on the data. See details for limitations of the backfitting procedure. Defaults to FALSE.
cv.num.iterations	integer specifying the number of times to iterate the backfitting process over all covariates. Defaults to 1.
backfit.iterate	boolean value specifying whether or not to iterate evaluations of the smooth coefficient estimator, for extra accuracy, during the cross-validated backfitting procedure. Defaults to FALSE.
backfit.maxiter	integer specifying the maximum number of times to iterate the evaluation of the smooth coefficient estimator in the attempt to obtain the desired accuracy. Defaults to 100.
backfit.tol	tolerance to determine convergence of iterated evaluations of the smooth coefficient estimator. Defaults to <code>.Machine\$double.eps</code> .

## Details

npscoefbw implements a variety of methods for semiparametric regression on multivariate ( $p + q$ -variate) explanatory data defined over a set of possibly continuous data. The approach is based on Li and Racine (2003) who employ ‘generalized product kernels’ that admit a mix of continuous and discrete data types.

Three classes of kernel estimators for the continuous data types are available: fixed, adaptive nearest-neighbor, and generalized nearest-neighbor. Adaptive nearest-neighbor bandwidths change with each sample realization in the set,  $x_i$ , when estimating the density at the point  $x$ . Generalized nearest-neighbor bandwidths change with the point at which the density is estimated,  $x$ . Fixed bandwidths are constant over the support of  $x$ .

npscoefbw may be invoked *either* with a formula-like symbolic description of variables on which bandwidth selection is to be performed *or* through a simpler interface whereby data is passed directly to the function via the `xdat`, `ydat`, and `zdat` parameters. Use of these two interfaces is **mutually exclusive**.

Data contained in the data frame `xdat` may be continuous and in `zdat` may be of mixed type. Data can be entered in an arbitrary order and data types will be detected automatically by the routine (see [np](#) for details).

Data for which bandwidths are to be estimated may be specified symbolically. A typical description has the form dependent data ~ parametric explanatory data | nonparametric explanatory data, where dependent data is a univariate response, and parametric explanatory data and nonparametric explanatory data are both series of variables specified by name, separated by the separation character ‘+’. For example, `y1 ~ x1 + x2 | z1` specifies that the bandwidth object for the smooth coefficient model with response `y1`, linear parametric regressors `x1` and `x2`, and nonparametric regressor (that is, the slope-changing variable) `z1` is to be estimated. See below for further examples. In the case where the nonparametric (slope-changing) variable is not specified, it is assumed to be the same as the parametric variable.

A variety of kernels may be specified by the user. Kernels implemented for continuous data types include the second, fourth, sixth, and eighth order Gaussian and Epanechnikov kernels, and the uniform kernel. Unordered discrete data types use a variation on Aitchison and Aitken’s (1976) kernel, while ordered data types use a variation of the Wang and van Ryzin (1981) kernel.

## Value

if `bwtype` is set to `fixed`, an object containing bandwidths (or scale factors if `bwscaling = TRUE`) is returned. If it is set to `generalized_nn` or `adaptive_nn`, then instead the  $k$ th nearest neighbors are returned for the continuous variables while the discrete kernel bandwidths are returned for the discrete variables. Bandwidths are stored in a vector under the component name `bw`. Backfitted bandwidths are stored under the component name `bw.fitted`.

The functions [predict](#), [summary](#), and [plot](#) support objects of this class.

## Usage Issues

If you are using data of mixed types, then it is advisable to use the [data.frame](#) function to construct your input data and not [cbind](#), since [cbind](#) will typically not work as intended on mixed data types and will coerce the data to the same type.

Caution: multivariate data-driven bandwidth selection methods are, by their nature, *computationally intensive*. Virtually all methods require dropping the  $i$ th observation from the data set, computing an object, repeating this for all observations in the sample, then averaging each of these leave-one-out estimates for a *given* value of the bandwidth vector, and only then repeating this a large number of times in order to conduct multivariate numerical minimization/maximization. Furthermore, due to the potential for local minima/maxima, *restarting this procedure a large number of times may often be necessary*. This can be frustrating for users possessing large datasets. For exploratory purposes, you may wish to override the default search tolerances, say, setting `optim.reltol=.1` and conduct multistarting (the default is to restart `min(5,ncol(zdat))` times). Once the procedure terminates, you can restart search with default tolerances using those bandwidths obtained from the less rigorous search (i.e., set `bws=bw` on subsequent calls to this routine where `bw` is the initial bandwidth object). A version of this package using the `Rmpi` wrapper is under development that allows one to deploy this software in a clustered computing environment to facilitate computation involving large datasets.

Support for backfitted bandwidths is experimental and is limited in functionality. The code does not support asymptotic standard errors or out of sample estimates with backfitting.

npsdeptest

---

*Kernel Consistent Serial Dependence Test for Univariate Nonlinear Processes*

---

## Description

npsdeptest implements the consistent metric entropy test of nonlinear serial dependence as described in Granger, Maasoumi and Racine (2004).

## Usage

```

npsdeptest(data = NULL,
            lag.num = 1,
            method = c("integration","summation"),
            bootstrap = TRUE,
            boot.num = 399,
            random.seed = 42)

```

## Arguments

data	a vector containing the variable that can be of type <a href="#">numeric</a> or <a href="#">ts</a> .
lag.num	an integer value specifying the maximum number of lags to use. Defaults to 1.
method	a character string used to specify whether to compute the integral version or the summation version of the statistic. Can be set as <code>integration</code> or <code>summation</code> (see below for details). Defaults to <code>integration</code> .
bootstrap	a logical value which specifies whether to conduct the bootstrap test or not. If set to <code>FALSE</code> , only the statistic will be computed. Defaults to <code>TRUE</code> .

boot.num	an integer value specifying the number of bootstrap replications to use. Defaults to 399.
random.seed	an integer used to seed R's random number generator. This is to ensure replicability. Defaults to 42.

### Details

npsdeptest computes the nonparametric metric entropy (normalized Hellinger of Granger, Maaoui and Racine (2004)) for testing for nonlinear serial dependence,  $D[f(y_t, \hat{y}_{t-k}), f(y_t) \times f(\hat{y}_{t-k})]$ . Default bandwidths are of the Kullback-Leibler variety obtained via likelihood cross-validation.

The test may be applied to a raw data series or to residuals of user estimated models.

The summation version of this statistic may be numerically unstable when data is sparse (the summation version involves division of densities while the integration version involves differences). Warning messages are produced should this occur ('integration recommended') and should be heeded.

### Value

npsdeptest returns an object of type deptest with the following components

Srho	the statistic vector Srho
Srho.cumulant	the cumulant statistic vector Srho.cumulant
Srho.bootstrap.mat	contains the bootstrap replications of Srho
Srho.cumulant.bootstrap.mat	contains the bootstrap replications of Srho.cumulant
P	the P-value vector of the Srho statistic vector
P.cumulant	the P-value vector of the cumulant Srho statistic vector
bootstrap	a logical value indicating whether bootstrapping was performed
boot.num	number of bootstrap replications
lag.num	the number of lags
bw.y	the numeric vector of bandwidths for data marginal density at lag num.lag
bw.y.lag	the numeric vector of bandwidths for lagged data marginal density at lag num.lag
bw.joint	the numeric matrix of bandwidths for data and lagged data joint density at lag num.lag

[summary](#) supports object of type deptest.

### Usage Issues

The integration version of the statistic uses multidimensional numerical methods from the **cu-bature** package. See **adaptIntegrate** for details. The integration version of the statistic will be substantially slower than the summation version, however, it will likely be both more accurate and powerful.

npseed

*Set Random Seed***Description**

npseed is a function which sets the random seed in the [np](#) C backend, resetting the random number generator.

**Usage**

```
npseed(seed)
```

**Arguments**

seed                      an integer seed for the random number generator.

**Details**

npseed provides an interface for setting the random seed (and resetting the random number generator) used by [np](#). The random number generator is used during the bandwidth search procedure to set the search starting point, and in subsequent searches when using multistarting, to avoid being trapped in local minima if the objective function is not globally concave.

Calling npseed will only affect the numerical search if it is performed by the C backend. The affected functions include: [npudensbw](#), [npcdensbw](#), [npregbw](#), [npplregbw](#), [npqreg](#), [npcmstest](#) (via [npregbw](#)), [npqcmstest](#) (via [npregbw](#)), [npsigtest](#) (via [npregbw](#)).

**Value**

None.

**Note**

This method currently only supports objects from the [np](#) library.

---

npsigtest

---

*Kernel Regression Significance Test with Mixed Data Types*

---

**Description**

npsigtest implements a consistent test of significance of an explanatory variable(s) in a nonparametric regression setting that is analogous to a simple  $t$ -test ( $F$ -test) in a parametric regression setting. The test is based on Racine, Hart, and Li (2006) and Racine (1997).

**Usage**

```
npsigtest(bws, ...)

## S3 method for class 'formula'
npsigtest(bws, data = NULL, ...)

## S3 method for class 'call'
npsigtest(bws, ...)

## S3 method for class 'npregression'
npsigtest(bws, ...)

## Default S3 method:
npsigtest(bws, xdat, ydat, ...)

## S3 method for class 'rbandwidth'
npsigtest(bws,
  xdat = stop("data xdat missing"),
  ydat = stop("data ydat missing"),
  boot.num = 399,
  boot.method = c("iid", "wild", "wild-rademacher", "pairwise"),
  boot.type = c("I", "II"),
  pivot=TRUE,
  joint=FALSE,
  index = seq(1, ncol(xdat)),
  random.seed = 42,
  ...)
```

**Arguments**

bws	a bandwidth specification. This can be set as a <code>rbandwidth</code> object returned from a previous invocation, or as a vector of bandwidths, with each element $i$ corresponding to the bandwidth for column $i$ in <code>xdat</code> . In either case, the bandwidth supplied will serve as a starting point in the numerical search for optimal bandwidths when using <code>boot.type="II"</code> . If specified as a vector, then additional arguments will need to be supplied as necessary to specify the bandwidth type, kernel types, selection methods, and so on.
data	an optional data frame, list or environment (or object coercible to a data frame by <code>as.data.frame</code> ) containing the variables in the model. If not found in data, the variables are taken from <code>environment(bws)</code> , typically the environment from which <code>npregbw</code> was called.
xdat	a $p$ -variate data frame of explanatory data (training data) used to calculate the regression estimators.
ydat	a one (1) dimensional numeric or integer vector of dependent data, each element $i$ corresponding to each observation (row) $i$ of <code>xdat</code> .
boot.method	a character string used to specify the bootstrap method for determining the null distribution. <code>pairwise</code> resamples pairwise, while the remaining methods use a residual bootstrap procedure. <code>iid</code> will generate independent identically distributed draws. <code>wild</code> will use a wild bootstrap. <code>wild-rademacher</code> will use a wild bootstrap with Rademacher variables. Defaults to <code>iid</code> .
boot.num	an integer value specifying the number of bootstrap replications to use. Defaults to 399.
boot.type	a character string specifying whether to use a 'Bootstrap I' or 'Bootstrap II' method (see Racine, Hart, and Li (2006) for details). The 'Bootstrap II' method re-runs cross-validation for each bootstrap replication and uses the new cross-validated bandwidth for variable $i$ and the original ones for the remaining variables. Defaults to <code>boot.type="I"</code> .
pivot	a logical value which specifies whether to bootstrap a pivotal statistic or not (pivoting is achieved by dividing gradient estimates by their asymptotic standard errors). Defaults to <code>TRUE</code> .
joint	a logical value which specifies whether to conduct a joint test or individual test. This is to be used in conjunction with <code>index</code> where <code>index</code> contains two or more integers corresponding to the variables being tested, where the integers correspond to the variables in the order in which they appear among the set of explanatory variables in the function call to <code>npreg/npregbw</code> . Defaults to <code>FALSE</code> .
index	a vector of indices for the columns of <code>xdat</code> for which the test of significance is to be conducted. Defaults to $(1, 2, \dots, p)$ where $p$ is the number of columns in <code>xdat</code> .
random.seed	an integer used to seed R's random number generator. This is to ensure replicability. Defaults to 42.
...	additional arguments supplied to specify the bandwidth type, kernel types, selection methods, and so on, detailed below.

## Details

npsigtest implements a variety of methods for computing the null distribution of the test statistic and allows the user to investigate the impact of a variety of default settings including whether or not to pivot the statistic (`pivot`), whether pairwise or residual resampling is to be used (`boot.method`), and whether or not to recompute the bandwidths for the variables being tested (`boot.type`), among others.

Defaults are chosen so as to provide reasonable behaviour in a broad range of settings and this involves a trade-off between computational expense and finite-sample performance. However, the default `boot.type="I"`, though computationally expedient, can deliver a test that can be slightly over-sized in small sample settings (e.g. at the 5% level the test might reject 8% of the time for samples of size  $n = 100$  for some data generating processes). If the default setting (`boot.type="I"`) delivers a P-value that is in the neighborhood (i.e. slightly smaller) of any classical level (e.g. 0.05) and you only have a modest amount of data, it might be prudent to re-run the test using the more computationally intensive `boot.type="II"` setting to confirm the original result. Note also that `boot.method="pairwise"` is not recommended for the multivariate local linear estimator due to substantial size distortions that may arise in certain cases.

## Value

npsigtest returns an object of type `sigtest`. [summary](#) supports `sigtest` objects. It has the following components:

In	the vector of statistics In
P	the vector of P-values for each statistic in In
In.bootstrap	contains a matrix of the bootstrap replications of the vector In, each column corresponding to replications associated with explanatory variables in <code>xdat</code> indexed by <code>index</code> (e.g., if you selected <code>index = c(1, 4)</code> then <code>In.bootstrap</code> will have two columns, the first being the bootstrap replications of In associated with variable 1, the second with variable 4).

## Usage Issues

If you are using data of mixed types, then it is advisable to use the [data.frame](#) function to construct your input data and not [cbind](#), since [cbind](#) will typically not work as intended on mixed data types and will coerce the data to the same type.

Caution: bootstrap methods are, by their nature, *computationally intensive*. This can be frustrating for users possessing large datasets. For exploratory purposes, you may wish to override the default number of bootstrap replications, say, setting them to `boot.num=99`. A version of this package using the `Rmpi` wrapper is under development that allows one to deploy this software in a clustered computing environment to facilitate computation involving large datasets.

## End(Not run)

```

---

npsymtest

---

*Kernel Consistent Density Asymmetry Test with Mixed Data Types*

---

## Description

npsymtest implements the consistent metric entropy test of asymmetry as described in Maasoumi and Racine (2009).

## Usage

```

npsymtest(data = NULL,
           method = c("integration", "summation"),
           boot.num = 399,
           bw = NULL,
           boot.method = c("iid", "geom"),

```

```
random.seed = 42,
...)
```

### Arguments

<code>data</code>	a vector containing the variable.
<code>method</code>	a character string used to specify whether to compute the integral version or the summation version of the statistic. Can be set as <code>integration</code> or <code>summation</code> (see below for details). Defaults to <code>integration</code> .
<code>boot.num</code>	an integer value specifying the number of bootstrap replications to use. Defaults to 399.
<code>bw</code>	a numeric (scalar) bandwidth. Defaults to plug-in (see details below).
<code>boot.method</code>	a character string used to specify the bootstrap method. Can be set as <code>iid</code> or <code>geom</code> (see below for details). Defaults to <code>iid</code> .
<code>random.seed</code>	an integer used to seed R's random number generator. This is to ensure replicability. Defaults to 42.
<code>...</code>	additional arguments supplied to specify the bandwidth type, kernel types, and so on. This is used since we specify <code>bw</code> as a numeric scalar and not a bandwidth object, and is of interest if you do not desire the default behaviours. To change the defaults, you may specify any of <code>bwscaling</code> , <code>bwtype</code> , <code>ckertype</code> , <code>ckerorder</code> , <code>ukertype</code> , <code>okertype</code> .

### Details

`npsymtest` computes the nonparametric metric entropy (normalized Hellinger of Granger, Maasoumi and Racine (2004)) for testing symmetry using the densities/probabilities of the data and the rotated data,  $D[f(y), f(\tilde{y})]$ . See Maasoumi and Racine (2009) for details. Default bandwidths are of the plug-in variety ([bw.SJ](#) for continuous variables and direct plug-in for discrete variables).

For bootstrapping the null distribution of the statistic, `iid` conducts simple random resampling, while `geom` conducts Politis and Romano's (1994) stationary bootstrap using automatic block length selection via the [b.star](#) function in the [np](#) package. See the **boot** package for details.

The summation version of this statistic may be numerically unstable when `y` is sparse (the summation version involves division of densities while the integration version involves differences). Warning messages are produced should this occur ('integration recommended') and should be heeded.

### Value

`npsymtest` returns an object of type `symtest` with the following components

<code>Srho</code>	the statistic <code>Srho</code>
<code>Srho.bootstrap</code>	contains the bootstrap replications of <code>Srho</code>
<code>P</code>	the P-value of the statistic
<code>boot.num</code>	number of bootstrap replications
<code>data.rotate</code>	the rotated data series
<code>bw</code>	the numeric (scalar) bandwidth

[summary](#) supports object of type `symtest`.

### Usage Issues

When using data of type `factor` it is crucial that the variable not be an alphabetic character string (i.e. the factor must be integer-valued). The rotation is conducted about the median after conversion to type `numeric` which is then converted back to type `factor`. Failure to do so will have unpredictable results. See the example below for proper usage.

---

nptgauss

*Truncated Second-order Gaussian Kernels*

---

## Description

nptgauss provides an interface for setting the truncation radius of the truncated second-order Gaussian kernel used by **np**.

## Usage

```
nptgauss(b)
```

## Arguments

**b**                      Truncation radius of the kernel.

## Details

nptgauss allows one to set the truncation radius of the truncated Gaussian kernel used by **np**, which defaults to 3. It automatically computes the constants describing the truncated gaussian kernel for the user.

We define the truncated gaussian kernel on the interval  $[-b, b]$  as:

$$K = \frac{\alpha}{\sqrt{2\pi}} \left( e^{-z^2/2} - e^{-b^2/2} \right)$$

The constant  $\alpha$  is computed as:

$$\alpha = \left[ \int_{-b}^b \frac{1}{\sqrt{2\pi}} \left( e^{-z^2/2} - e^{-b^2/2} \right) \right]^{-1}$$

Given these definitions, the derivative kernel is simply:

$$K' = (-z) \frac{\alpha}{\sqrt{2\pi}} e^{-z^2/2}$$

The CDF kernel is:

$$G = \frac{\alpha}{2} \operatorname{erf}(z/\sqrt{2}) + \frac{1}{2} - c_0 z$$

The convolution kernel on  $[-2b, 0]$  has the general form:

$$H_- = a_0 \operatorname{erf}(z/2 + b) e^{-z^2/4} + a_1 z + a_2 \operatorname{erf}((z + b)/\sqrt{2}) - c_0$$

and on  $[0, 2b]$  it is:

$$H_+ = -a_0 \operatorname{erf}(z/2 - b) e^{-z^2/4} - a_1 z - a_2 \operatorname{erf}((z - b)/\sqrt{2}) - c_0$$

where  $a_0$  is determined by the normalisation condition on  $H$ ,  $a_2$  is determined by considering the value of the kernel at  $z = 0$  and  $a_1$  is determined by the requirement that  $H = 0$  at  $[-2b, 2b]$ .

```

npudens

*Kernel Density Estimation with Mixed Data Types***Description**

npudens computes kernel unconditional density estimates on evaluation data, given a set of training data and a bandwidth specification (a bandwidth object or a bandwidth vector, bandwidth type, and kernel type) using the method of Li and Racine (2003).

**Usage**

```
npudens(bws, ...)

## S3 method for class 'formula'
npudens(bws, data = NULL, newdata = NULL, ...)

## S3 method for class 'bandwidth'
npudens(bws,
        tdat = stop("invoked without training data 'tdat'"),
        edat,
        ...)

## S3 method for class 'call'
npudens(bws, ...)

## Default S3 method:
npudens(bws, tdat, ...)
```

**Arguments**

bws	a bandwidth specification. This can be set as a bandwidth object returned from an invocation of <a href="#">npudensbw</a> , or as a $p$ -vector of bandwidths, with an element for each variable in the training data. If specified as a vector, then additional arguments will need to be supplied as necessary to change them from the defaults to specify the bandwidth type, kernel types, training data, and so on.
...	additional arguments supplied to specify, the training data, the bandwidth type, kernel types, and so on. This is necessary if you specify bws as a $p$ -vector and not a bandwidth object, and you do not desire the default behaviours. To do this, you may specify any of bwscaling, bwtype, ckertype, ckerorder, ukertype, okertype, as described in <a href="#">npudensbw</a> .
tdat	a $p$ -variate data frame of sample realizations (training data) used to estimate the density. Defaults to the training data used to compute the bandwidth object.
edat	a $p$ -variate data frame of density evaluation points. By default, evaluation takes place on the data provided by tdat.

data	an optional data frame, list or environment (or object coercible to a data frame by <a href="#">as.data.frame</a> ) containing the variables in the model. If not found in data, the variables are taken from <code>environment(bws)</code> , typically the environment from which <code>npudensbw</code> was called.
newdata	An optional data frame in which to look for evaluation data. If omitted, the training data are used.

## Details

Typical usages are (see below for a complete list of options and also the examples at the end of this help file)

Usage 1: first compute the bandwidth object via `npudensbw` and then compute the density:

```
bw <- npudensbw(~y)
fhat <- npudens(bw)
```

Usage 2: alternatively, compute the bandwidth object indirectly:

```
fhat <- npudens(~y)
```

Usage 3: modify the default kernel and order:

```
fhat <- npudens(~y, ckertype="epanechnikov", ckerorder=4)
```

Usage 4: use the data frame interface rather than the formula interface:

```
fhat <- npudens(tdat = y, ckertype="epanechnikov", ckerorder=4)
```

`npudens` implements a variety of methods for estimating multivariate density functions ( $p$ -variate) defined over a set of possibly continuous and/or discrete (unordered, ordered) data. The approach is based on Li and Racine (2003) who employ ‘generalized product kernels’ that admit a mix of continuous and discrete data types.

Three classes of kernel estimators for the continuous data types are available: fixed, adaptive nearest-neighbor, and generalized nearest-neighbor. Adaptive nearest-neighbor bandwidths change with each sample realization in the set,  $x_i$ , when estimating the density at the point  $x$ . Generalized nearest-neighbor bandwidths change with the point at which the density is estimated,  $x$ . Fixed bandwidths are constant over the support of  $x$ .

Data contained in the data frame `tdat` (and also `edat`) may be a mix of continuous (default), unordered discrete (to be specified in the data frame `tdat` using the [factor](#) command), and ordered discrete (to be specified in the data frame `tdat` using the [ordered](#) command). Data can be entered in an arbitrary order and data types will be detected automatically by the routine (see [np](#) for details).

A variety of kernels may be specified by the user. Kernels implemented for continuous data types include the second, fourth, sixth, and eighth order Gaussian and Epanechnikov kernels, and the uniform kernel. Unordered discrete data types use a variation on Aitchison and Aitken’s (1976) kernel, while ordered data types use a variation of the Wang and van Ryzin (1981) kernel.

**Value**

npudens returns a npdensity object. The generic accessor functions `fitted`, and `se`, extract estimated values and asymptotic standard errors on estimates, respectively, from the returned object. Furthermore, the functions `predict`, `summary` and `plot` support objects of both classes. The returned objects have the following components:

<code>eval</code>	the evaluation points.
<code>dens</code>	estimation of the density at the evaluation points
<code>derr</code>	standard errors of the density estimates
<code>log_likelihood</code>	log likelihood of the density estimates

**Usage Issues**

If you are using data of mixed types, then it is advisable to use the `data.frame` function to construct your input data and not `cbind`, since `cbind` will typically not work as intended on mixed data types and will coerce the data to the same type.

## Arguments

formula	a symbolic description of variables on which bandwidth selection is to be performed. The details of constructing a formula are described below.
data	an optional data frame, list or environment (or object coercible to a data frame by <a href="#">as.data.frame</a> ) containing the variables in the model. If not found in data, the variables are taken from <code>environment(formula)</code> , typically the environment from which the function is called.
subset	an optional vector specifying a subset of observations to be used in the fitting process.
na.action	a function which indicates what should happen when the data contain NAs. The default is set by the <a href="#">na.action</a> setting of options, and is <a href="#">na.fail</a> if that is unset. The (recommended) default is <a href="#">na.omit</a> .
call	the original function call. This is passed internally by <a href="#">np</a> when a bandwidth search has been implied by a call to another function. It is not recommended that the user set this.
dat	a $p$ -variate data frame on which bandwidth selection will be performed. The data types may be continuous, discrete (unordered and ordered factors), or some combination thereof.
bws	a bandwidth specification. This can be set as a bandwidth object returned from a previous invocation, or as a vector of bandwidths, with each element $i$ corresponding to the bandwidth for column $i$ in <code>dat</code> . In either case, the bandwidth supplied will serve as a starting point in the numerical search for optimal

	bandwidths. If specified as a vector, then additional arguments will need to be supplied as necessary to specify the bandwidth type, kernel types, selection methods, and so on. This can be left unset.
...	additional arguments supplied to specify the bandwidth type, kernel types, selection methods, and so on, detailed below.
bwmethod	a character string specifying the bandwidth selection method. <code>cv.ml</code> specifies likelihood cross-validation, <code>cv.ls</code> specifies least-squares cross-validation, and <code>normal-reference</code> just computes the ‘rule-of-thumb’ bandwidth $h_j$ using the standard formula $h_j = 1.06\sigma_j n^{-1/(2P+l)}$ , where $\sigma_j$ is an adaptive measure of spread of the $j$ th continuous variable defined as $\min(\text{standard deviation}, \text{mean absolute deviation}/1.4826, \text{interquartile range}/1.349)$ , $n$ the number of observations, $P$ the order of the kernel, and $l$ the number of continuous variables. Note that when there exist factors and the normal-reference rule is used, there is zero smoothing of the factors. Defaults to <code>cv.ml</code> .
bwscaling	a logical value that when set to <code>TRUE</code> the supplied bandwidths are interpreted as ‘scale factors’ ( $c_j$ ), otherwise when the value is <code>FALSE</code> they are interpreted as ‘raw bandwidths’ ( $h_j$ for continuous data types, $\lambda_j$ for discrete data types). For continuous data types, $c_j$ and $h_j$ are related by the formula $h_j = c_j\sigma_j n^{-1/(2P+l)}$ , where $\sigma_j$ is an adaptive measure of spread of the $j$ th continuous variable defined as $\min(\text{standard deviation}, \text{mean absolute deviation}/1.4826, \text{interquartile range}/1.349)$ , $n$ the number of observations, $P$ the order of the kernel, and $l$ the number of continuous variables. For discrete data types, $c_j$ and $h_j$ are related by the formula $h_j = c_j n^{-2/(2P+l)}$ , where here $j$ denotes discrete variable $j$ . Defaults to <code>FALSE</code> .
bwtype	character string used for the continuous variable bandwidth type, specifying the type of bandwidth to compute and return in the bandwidth object. Defaults to <code>fixed</code> . Option summary: <code>fixed</code> : compute fixed bandwidths <code>generalized_nn</code> : compute generalized nearest neighbors <code>adaptive_nn</code> : compute adaptive nearest neighbors
bandwidth.compute	a logical value which specifies whether to do a numerical search for bandwidths or not. If set to <code>FALSE</code> , a bandwidth object will be returned with bandwidths set to those specified in <code>bws</code> . Defaults to <code>TRUE</code> .
ckertype	character string used to specify the continuous kernel type. Can be set as <code>gaussian</code> , <code>epanechnikov</code> , or <code>uniform</code> . Defaults to <code>gaussian</code> .
ckerorder	numeric value specifying kernel order (one of (2, 4, 6, 8)). Kernel order specified along with a uniform continuous kernel type will be ignored. Defaults to 2.
ukertype	character string used to specify the unordered categorical kernel type. Can be set as <code>aitchisonaitken</code> or <code>liracine</code> .
okertype	character string used to specify the ordered categorical kernel type. Can be set as <code>wangvanryzin</code> or <code>liracine</code> .
nmulti	integer number of times to restart the process of finding extrema of the cross-validation function from different (random) initial points.

<code>remin</code>	a logical value which when set as TRUE the search routine restarts from located minima for a minor gain in accuracy. Defaults to TRUE.
<code>itmax</code>	integer number of iterations before failure in the numerical optimization routine. Defaults to 10000.
<code>ftol</code>	fractional tolerance on the value of the cross-validation function evaluated at located minima (of order the machine precision or perhaps slightly larger so as not to be diddled by roundoff). Defaults to $1.490116e-07$ ( $1.0e+01*\sqrt{.Machine\$double.eps}$ ).
<code>tol</code>	tolerance on the position of located minima of the cross-validation function (tol should generally be no smaller than the square root of your machine's floating point precision). Defaults to $1.490116e-04$ ( $1.0e+04*\sqrt{.Machine\$double.eps}$ ).
<code>small</code>	a small number used to bracket a minimum (it is hopeless to ask for a bracketing interval of width less than $\sqrt{\epsilon}$ times its central value, a fractional width of only about $10^{-4}$ (single precision) or $3 \times 10^{-8}$ (double precision)). Defaults to $1.490116e-05$ ( $1.0e+03*\sqrt{.Machine\$double.eps}$ ).
<code>lbc.dir, dfc.dir, cfac.dir, initc.dir</code>	lower bound, chi-square degrees of freedom, stretch factor, and initial non-random values for direction set search for Powell's algorithm for numeric variables. See Details
<code>lbd.dir, hbd.dir, dfac.dir, initd.dir</code>	lower bound, upper bound, stretch factor, and initial non-random values for direction set search for Powell's algorithm for categorical variables. See Details
<code>lbc.init, hbc.init, cfac.init</code>	lower bound, upper bound, and non-random initial values for scale factors for numeric variables for Powell's algorithm. See Details
<code>lbd.init, hbd.init, dfac.init</code>	lower bound, upper bound, and non-random initial values for scale factors for categorical variables for Powell's algorithm. See Details
<code>scale.init.categorical.sample</code>	a logical value that when set to TRUE scales <code>lbd.dir</code> , <code>hbd.dir</code> , <code>dfac.dir</code> , and <code>initd.dir</code> by $n^{-2/(2P+l)}$ , $n$ the number of observations, $P$ the order of the kernel, and $l$ the number of numeric variables. See Details

## Details

Typical usages are (see below for a complete list of options and also the examples at the end of this help file)

Usage 1: compute a bandwidth object using the formula interface:

```
bw <- npudensbw(~y)
```

Usage 2: compute a bandwidth object using the data frame interface and change the default kernel and order:

```
fhat <- npudensbw(tdat = y, ckertype="epanechnikov", ckerorder=4)
```

npudensbw implements a variety of methods for choosing bandwidths for multivariate ( $p$ -variate) distributions defined over a set of possibly continuous and/or discrete (unordered, ordered) data. The approach is based on Li and Racine (2003) who employ ‘generalized product kernels’ that admit a mix of continuous and discrete data types.

The cross-validation methods employ multivariate numerical search algorithms (direction set (Powell’s) methods in multidimensions).

Bandwidths can (and will) differ for each variable which is, of course, desirable.

Three classes of kernel estimators for the continuous data types are available: fixed, adaptive nearest-neighbor, and generalized nearest-neighbor. Adaptive nearest-neighbor bandwidths change with each sample realization in the set,  $x_i$ , when estimating the density at the point  $x$ . Generalized nearest-neighbor bandwidths change with the point at which the density is estimated,  $x$ . Fixed bandwidths are constant over the support of  $x$ .

npudensbw may be invoked *either* with a formula-like symbolic description of variables on which bandwidth selection is to be performed *or* through a simpler interface whereby data is passed directly to the function via the `dat` parameter. Use of these two interfaces is **mutually exclusive**.

Data contained in the data frame `dat` may be a mix of continuous (default), unordered discrete (to be specified in the data frame `dat` using `factor`), and ordered discrete (to be specified in the data frame `dat` using `ordered`). Data can be entered in an arbitrary order and data types will be detected automatically by the routine (see [np](#) for details).

Data for which bandwidths are to be estimated may be specified symbolically. A typical description has the form `~ data`, where `data` is a series of variables specified by name, separated by the separation character `+`. For example, `~ x + y` specifies that the bandwidths for the joint distribution of variables `x` and `y` are to be estimated. See below for further examples.

A variety of kernels may be specified by the user. Kernels implemented for continuous data types include the second, fourth, sixth, and eighth order Gaussian and Epanechnikov kernels, and the uniform kernel. Unordered discrete data types use a variation on Aitchison and Aitken’s (1976) kernel, while ordered data types use a variation of the Wang and van Ryzin (1981) kernel.

The optimizer invoked for search is Powell’s conjugate direction method which requires the setting of (non-random) initial values and search directions for bandwidths, and, when restarting, random values for successive invocations. Bandwidths for numeric variables are scaled by robust measures of spread, the sample size, and the number of numeric variables where appropriate. Two sets of parameters for bandwidths for numeric can be modified, those for initial values for the parameters themselves, and those for the directions taken (Powell’s algorithm does not involve explicit computation of the function’s gradient). The default values are set by considering search performance for a variety of difficult test cases and simulated cases. We highly recommend restarting search a large number of times to avoid the presence of local minima (achieved by modifying `nmulti`). Further refinement for difficult cases can be achieved by modifying these sets of parameters. However, these parameters are intended more for the authors of the package to enable ‘tuning’ for various methods rather than for the user themselves.

## Value

npudensbw returns a bandwidth object, with the following components:

<code>bw</code>	bandwidth(s), scale factor(s) or nearest neighbours for the data, <code>dat</code>
<code>fval</code>	objective function value at minimum

if `bwtype` is set to `fixed`, an object containing bandwidths, of class `bandwidth` (or scale factors if `bwscaling = TRUE`) is returned. If it is set to `generalized_nn` or `adaptive_nn`, then instead the  $k$ th nearest neighbors are returned for the continuous variables while the discrete kernel bandwidths are returned for the discrete variables. Bandwidths are stored under the component name `bw`, with each element  $i$  corresponding to column  $i$  of input data `dat`.

The functions `predict`, `summary` and `plot` support objects of type `bandwidth`.

### Usage Issues

If you are using data of mixed types, then it is advisable to use the `data.frame` function to construct your input data and not `cbind`, since `cbind` will typically not work as intended on mixed data types and will coerce the data to the same type.

Caution: multivariate data-driven bandwidth selection methods are, by their nature, *computationally intensive*. Virtually all methods require dropping the  $i$ th observation from the data set, computing an object, repeating this for all observations in the sample, then averaging each of these leave-one-out estimates for a *given* value of the bandwidth vector, and only then repeating this a large number of times in order to conduct multivariate numerical minimization/maximization. Furthermore, due to the potential for local minima/maxima, *restarting this procedure a large number of times may often be necessary*. This can be frustrating for users possessing large datasets. For exploratory purposes, you may wish to override the default search tolerances, say, setting `ftol=.01` and `tol=.01` and conduct multistarting (the default is to restart `min(5, ncol(dat))` times) as is done for a number of examples. Once the procedure terminates, you can restart search with default tolerances using those bandwidths obtained from the less rigorous search (i.e., set `bws=bw` on subsequent calls to this routine where `bw` is the initial bandwidth object). A version of this package using the `Rmpi` wrapper is under development that allows one to deploy this software in a clustered computing environment to facilitate computation involving large datasets.

npudist

---

*Kernel Distribution Estimation with Mixed Data Types*

---

## Description

npudist computes kernel unconditional cumulative distribution estimates on evaluation data, given a set of training data and a bandwidth specification (a dbandwidth object or a bandwidth vector, bandwidth type, and kernel type) using the method of Li, Li and Racine (2017).

## Usage

```
npudist(bws, ...)

## S3 method for class 'formula'
npudist(bws, data = NULL, newdata = NULL, ...)

## S3 method for class 'dbandwidth'
npudist(bws,
        tdat = stop("invoked without training data 'tdat'"),
        edat,
        ...)

## S3 method for class 'call'
npudist(bws, ...)

## Default S3 method:
npudist(bws, tdat, ...)
```

## Arguments

bws	a dbandwidth specification. This can be set as a dbandwidth object returned from an invocation of <a href="#">npudistbw</a> , or as a $p$ -vector of bandwidths, with an element for each variable in the training data. If specified as a vector, then additional arguments will need to be supplied as necessary to change them from the defaults to specify the bandwidth type, kernel types, training data, and so on.
...	additional arguments supplied to specify the training data, the bandwidth type, kernel types, and so on. This is necessary if you specify bws as a $p$ -vector and not a dbandwidth object, and you do not desire the default behaviours. To do this, you may specify any of bwscaling, bwtype, ckertype, ckerorder, okertype, as described in <a href="#">npudistbw</a> .
tdat	a $p$ -variate data frame of sample realizations (training data) used to estimate the cumulative distribution. Defaults to the training data used to compute the bandwidth object.

edat	a $p$ -variate data frame of cumulative distribution evaluation points. By default, evaluation takes place on the data provided by tdat.
data	an optional data frame, list or environment (or object coercible to a data frame by <a href="#">as.data.frame</a> ) containing the variables in the model. If not found in data, the variables are taken from environment(bws), typically the environment from which <a href="#">npudistbw</a> was called.
newdata	An optional data frame in which to look for evaluation data. If omitted, the training data are used.

## Details

Typical usages are (see below for a complete list of options and also the examples at the end of this help file)

Usage 1: first compute the bandwidth object via npudistbw and then compute the cumulative distribution:

```
bw <- npudistbw(~y)
Fhat <- npudist(bw)
```

Usage 2: alternatively, compute the bandwidth object indirectly:

```
Fhat <- npudist(~y)
```

Usage 3: modify the default kernel and order:

```
Fhat <- npudist(~y, ckertype="epanechnikov", ckerorder=4)
```

Usage 4: use the data frame interface rather than the formula interface:

```
Fhat <- npudist(tdat = y, ckertype="epanechnikov", ckerorder=4)
```

npudist implements a variety of methods for estimating multivariate cumulative distributions ( $p$ -variate) defined over a set of possibly continuous and/or discrete (ordered) data. The approach is based on Li and Racine (2003) who employ ‘generalized product kernels’ that admit a mix of continuous and discrete data types.

Three classes of kernel estimators for the continuous data types are available: fixed, adaptive nearest-neighbor, and generalized nearest-neighbor. Adaptive nearest-neighbor bandwidths change with each sample realization in the set,  $x_i$ , when estimating the cumulative distribution at the point  $x$ . Generalized nearest-neighbor bandwidths change with the point at which the cumulative distribution is estimated,  $x$ . Fixed bandwidths are constant over the support of  $x$ .

Data contained in the data frame tdat (and also edat) may be a mix of continuous (default) and ordered discrete (to be specified in the data frame tdat using the [ordered](#) command). Data can be entered in an arbitrary order and data types will be detected automatically by the routine (see [np](#) for details).

A variety of kernels may be specified by the user. Kernels implemented for continuous data types include the second, fourth, sixth, and eighth-order Gaussian and Epanechnikov kernels, and the uniform kernel. Ordered data types use a variation of the Wang and van Ryzin (1981) kernel.

## Value

`npudist` returns a `npdistribution` object. The generic accessor functions `fitted` and `se` extract estimated values and asymptotic standard errors on estimates, respectively, from the returned object. Furthermore, the functions `predict`, `summary` and `plot` support objects of both classes. The returned objects have the following components:

<code>eval</code>	the evaluation points.
<code>dist</code>	estimate of the cumulative distribution at the evaluation points
<code>derr</code>	standard errors of the cumulative distribution estimates

## Usage Issues

If you are using data of mixed types, then it is advisable to use the `data.frame` function to construct your input data and not `cbind`, since `cbind` will typically not work as intended on mixed data types and will coerce the data to the same type.

### Arguments

formula	a symbolic description of variables on which bandwidth selection is to be performed. The details of constructing a formula are described below.
data	an optional data frame, list or environment (or object coercible to a data frame by <a href="#">as.data.frame</a> ) containing the variables in the model. If not found in data, the variables are taken from <code>environment(formula)</code> , typically the environment from which the function is called.
subset	an optional vector specifying a subset of observations to be used in the fitting process.
na.action	a function which indicates what should happen when the data contain NAs. The default is set by the <a href="#">na.action</a> setting of options, and is <a href="#">na.fail</a> if that is unset. The (recommended) default is <a href="#">na.omit</a> .
call	the original function call. This is passed internally by <a href="#">np</a> when a bandwidth search has been implied by a call to another function. It is not recommended that the user set this.

<code>gdata</code>	a grid of data on which the indicator function for least-squares cross-validation is to be computed (can be the sample or a grid of quantiles).
<code>dat</code>	a $p$ -variate data frame on which bandwidth selection will be performed. The data types may be continuous, discrete (ordered factors), or some combination thereof.
<code>bws</code>	a bandwidth specification. This can be set as a bandwidth object returned from a previous invocation, or as a vector of bandwidths, with each element $i$ corresponding to the bandwidth for column $i$ in <code>dat</code> . In either case, the bandwidth supplied will serve as a starting point in the numerical search for optimal bandwidths. If specified as a vector, then additional arguments will need to be supplied as necessary to specify the bandwidth type, kernel types, selection methods, and so on. This can be left unset.
<code>gdat</code>	a grid of data on which the indicator function for least-squares cross-validation is to be computed (can be the sample or a grid of quantiles).
<code>...</code>	additional arguments supplied to specify the bandwidth type, kernel types, selection methods, and so on, detailed below.
<code>bwmethod</code>	a character string specifying the bandwidth selection method. <code>cv.cdf</code> specifies least-squares cross-validation for cumulative distribution functions (Li, Li and Racine (2017)), and <code>normal-reference</code> just computes the ‘rule-of-thumb’ bandwidth $h_j$ using the standard formula $h_j = 1.587\sigma_j n^{-1/(P+l)}$ , where $\sigma_j$ is an adaptive measure of spread of the $j$ th continuous variable defined as $\min(\text{standard deviation}, \text{mean absolute deviation}/1.4826, \text{interquartile range}/1.349)$ , $n$ the number of observations, $P$ the order of the kernel, and $l$ the number of continuous variables. Note that when there exist factors and the normal-reference rule is used, there is zero smoothing of the factors. Defaults to <code>cv.cdf</code> .
<code>bwscaling</code>	a logical value that when set to <code>TRUE</code> the supplied bandwidths are interpreted as ‘scale factors’ ( $c_j$ ), otherwise when the value is <code>FALSE</code> they are interpreted as ‘raw bandwidths’ ( $h_j$ for continuous data types, $\lambda_j$ for discrete data types). For continuous data types, $c_j$ and $h_j$ are related by the formula $h_j = c_j \sigma_j n^{-1/(P+l)}$ , where $\sigma_j$ is an adaptive measure of spread of the $j$ th continuous variable defined as $\min(\text{standard deviation}, \text{mean absolute deviation}/1.4826, \text{interquartile range}/1.349)$ , $n$ the number of observations, $P$ the order of the kernel, and $l$ the number of continuous variables. For discrete data types, $c_j$ and $h_j$ are related by the formula $h_j = c_j n^{-2/(P+l)}$ , where here $j$ denotes discrete variable $j$ . Defaults to <code>FALSE</code> .
<code>bwtype</code>	character string used for the continuous variable bandwidth type, specifying the type of bandwidth to compute and return in the bandwidth object. Defaults to <code>fixed</code> . Option summary: <code>fixed</code> : compute fixed bandwidths <code>generalized_nn</code> : compute generalized nearest neighbors <code>adaptive_nn</code> : compute adaptive nearest neighbors
<code>bandwidth.compute</code>	a logical value which specifies whether to do a numerical search for bandwidths or not. If set to <code>FALSE</code> , a bandwidth object will be returned with bandwidths set to those specified in <code>bws</code> . Defaults to <code>TRUE</code> .
<code>ckertype</code>	character string used to specify the continuous kernel type. Can be set as <code>gaussian</code> , <code>epanechnikov</code> , or <code>uniform</code> . Defaults to <code>gaussian</code> .

ckerorder	numeric value specifying kernel order (one of (2, 4, 6, 8)). Kernel order specified along with a uniform continuous kernel type will be ignored. Defaults to 2.
okertype	character string used to specify the ordered categorical kernel type. Can be set as wangvanryzin.
nmulti	integer number of times to restart the process of finding extrema of the cross-validation function from different (random) initial points.
remin	a logical value which when set as TRUE the search routine restarts from located minima for a minor gain in accuracy. Defaults to TRUE.
itmax	integer number of iterations before failure in the numerical optimization routine. Defaults to 10000.
do.full.integral	a logical value which when set as TRUE evaluates the moment-based integral on the entire sample. Defaults to FALSE.
ngrid	integer number of grid points to use when computing the moment-based integral. Defaults to 100.
ftol	fractional tolerance on the value of the cross-validation function evaluated at located minima (of order the machine precision or perhaps slightly larger so as not to be diddled by roundoff). Defaults to $1.490116e-07$ ( $1.0e+01*\sqrt{.Machine\$double.eps}$ ).
tol	tolerance on the position of located minima of the cross-validation function (tol should generally be no smaller than the square root of your machine's floating point precision). Defaults to $1.490116e-04$ ( $1.0e+04*\sqrt{.Machine\$double.eps}$ ).
small	a small number used to bracket a minimum (it is hopeless to ask for a bracketing interval of width less than $\sqrt{\epsilon}$ times its central value, a fractional width of only about $10^{-4}$ (single precision) or $3 \times 10^{-8}$ (double precision)). Defaults to $1.490116e-05$ ( $1.0e+03*\sqrt{.Machine\$double.eps}$ ).
lbc.dir, dfc.dir, cfac.dir, initc.dir	lower bound, chi-square degrees of freedom, stretch factor, and initial non-random values for direction set search for Powell's algorithm for numeric variables. See Details
lbd.dir, hbd.dir, dfac.dir, initd.dir	lower bound, upper bound, stretch factor, and initial non-random values for direction set search for Powell's algorithm for categorical variables. See Details
lbc.init, hbc.init, cfac.init	lower bound, upper bound, and non-random initial values for scale factors for numeric variables for Powell's algorithm. See Details
lbd.init, hbd.init, dfac.init	lower bound, upper bound, and non-random initial values for scale factors for categorical variables for Powell's algorithm. See Details
scale.init.categorical.sample	a logical value that when set to TRUE scales lbd.dir, hbd.dir, dfac.dir, and initd.dir by $n^{-2/(2P+l)}$ , $n$ the number of observations, $P$ the order of the kernel, and $l$ the number of numeric variables. See Details
memfac	The algorithm to compute the least-squares objective function uses a block-based algorithm to eliminate or minimize redundant kernel evaluations. Due

to memory, hardware and software constraints, a maximum block size must be imposed by the algorithm. This block size is roughly equal to  $\text{memfac} \times 10^5$  elements. Empirical tests on modern hardware find that a memfac of 500 performs well. If you experience out of memory errors, or strange behaviour for large data sets (>100k elements) setting memfac to a lower value may fix the problem.

## Details

Typical usages are (see below for a complete list of options and also the examples at the end of this help file)

Usage 1: compute a bandwidth object using the formula interface:

```
bw <- npudistbw(~y)
```

Usage 2: compute a bandwidth object using the data frame interface and change the default kernel and order:

```
Fhat <- npudistbw(tdat = y, ckertype="epanechnikov", ckerorder=4)
```

npudistbw implements a variety of methods for choosing bandwidths for multivariate ( $p$ -variate) distributions defined over a set of possibly continuous and/or discrete (ordered) data. The approach is based on Li and Racine (2003) who employ ‘generalized product kernels’ that admit a mix of continuous and discrete data types.

The cross-validation methods employ multivariate numerical search algorithms (direction set (Powell’s) methods in multidimensions).

Bandwidths can (and will) differ for each variable which is, of course, desirable.

Three classes of kernel estimators for the continuous data types are available: fixed, adaptive nearest-neighbor, and generalized nearest-neighbor. Adaptive nearest-neighbor bandwidths change with each sample realization in the set,  $x_i$ , when estimating the cumulative distribution at the point  $x$ . Generalized nearest-neighbor bandwidths change with the point at which the cumulative distribution is estimated,  $x$ . Fixed bandwidths are constant over the support of  $x$ .

npudistbw may be invoked *either* with a formula-like symbolic description of variables on which bandwidth selection is to be performed *or* through a simpler interface whereby data is passed directly to the function via the dat parameter. Use of these two interfaces is **mutually exclusive**.

Data contained in the data frame dat may be a mix of continuous (default) and ordered discrete (to be specified in the data frame dat using [ordered](#)). Data can be entered in an arbitrary order and data types will be detected automatically by the routine (see [np](#) for details).

Data for which bandwidths are to be estimated may be specified symbolically. A typical description has the form  $\sim \text{data}$ , where data is a series of variables specified by name, separated by the separation character ‘+’. For example,  $\sim x + y$  specifies that the bandwidths for the joint distribution of variables  $x$  and  $y$  are to be estimated. See below for further examples.

A variety of kernels may be specified by the user. Kernels implemented for continuous data types include the second, fourth, sixth, and eighth-order Gaussian and Epanechnikov kernels, and the uniform kernel. Ordered data types use a variation of the Wang and van Ryzin (1981) kernel.

The optimizer invoked for search is Powell's conjugate direction method which requires the setting of (non-random) initial values and search directions for bandwidths, and when restarting, random values for successive invocations. Bandwidths for numeric variables are scaled by robust measures of spread, the sample size, and the number of numeric variables where appropriate. Two sets of parameters for bandwidths for numeric can be modified, those for initial values for the parameters themselves, and those for the directions taken (Powell's algorithm does not involve explicit computation of the function's gradient). The default values are set by considering search performance for a variety of difficult test cases and simulated cases. We highly recommend restarting search a large number of times to avoid the presence of local minima (achieved by modifying `nmulti`). Further refinement for difficult cases can be achieved by modifying these sets of parameters. However, these parameters are intended more for the authors of the package to enable 'tuning' for various methods rather than for the user them self.

## Value

`npudistbw` returns a bandwidth object with the following components:

<code>bw</code>	bandwidth(s), scale factor(s) or nearest neighbours for the data, <code>dat</code>
<code>fval</code>	objective function value at minimum

if `bwtype` is set to `fixed`, an object containing bandwidths, of class `bandwidth` (or scale factors if `bwscaling = TRUE`) is returned. If it is set to `generalized_nn` or `adaptive_nn`, then instead the  $k$ th nearest neighbors are returned for the continuous variables while the discrete kernel bandwidths are returned for the discrete variables. Bandwidths are stored under the component name `bw`, with each element  $i$  corresponding to column  $i$  of input data `dat`.

The functions `predict`, `summary` and `plot` support objects of type `bandwidth`.

## Usage Issues

If you are using data of mixed types, then it is advisable to use the `data.frame` function to construct your input data and not `cbind`, since `cbind` will typically not work as intended on mixed data types and will coerce the data to the same type.

Caution: multivariate data-driven bandwidth selection methods are, by their nature, *computationally intensive*. Virtually all methods require dropping the  $i$ th observation from the data set, computing an object, repeating this for all observations in the sample, then averaging each of these leave-one-out estimates for a *given* value of the bandwidth vector, and only then repeating this a large number of times in order to conduct multivariate numerical minimization/maximization. Furthermore, due to the potential for local minima/maxima, *restarting this procedure a large number of times may often be necessary*. This can be frustrating for users possessing large datasets. For exploratory purposes, you may wish to override the default search tolerances, say, setting `ftol=.01` and `tol=.01` and conduct multistarting (the default is to restart `min(5, ncol(dat))` times) as is done for a number of examples. Once the procedure terminates, you can restart search with default tolerances using those bandwidths obtained from the less rigorous search (i.e., set `bws=bw` on subsequent calls to this routine where `bw` is the initial bandwidth object). A version of this package using the `Rmpi` wrapper is under development that allows one to deploy this software in a clustered computing environment to facilitate computation involving large datasets.

---

npuniden.boundary

---

*Kernel Bounded Univariate Density Estimation Via Boundary Kernel Functions*

---

## Description

npuniden.boundary computes kernel univariate unconditional density estimates given a vector of continuously distributed training data and, optionally, a bandwidth (otherwise least squares cross-validation is used for its selection). Lower and upper bounds  $[a, b]$  can be supplied (default is the empirical support  $[\min(X), \max(X)]$ ) and if  $a$  is set to  $-\text{Inf}$  there is only one bound on the right, while if  $b$  is set to  $\text{Inf}$  there is only one bound on the left. If  $a$  is set to  $-\text{Inf}$  and  $b$  to  $\text{Inf}$  and the Gaussian type 1 kernel function is used, this will deliver the standard unadjusted kernel density estimate.

**Usage**

```
npuniden.boundary(X = NULL,
                  Y = NULL,
                  h = NULL,
                  a = min(X),
                  b = max(X),
                  bwmethod = c("cv.ls", "cv.ml"),
                  cv = c("grid-hybrid", "numeric"),
                  grid = NULL,
                  kertype = c("gaussian1", "gaussian2",
                              "beta1", "beta2",
                              "fb", "fbl", "fbu",
                              "rigaussian", "gamma"),
                  nmulti = 5,
                  proper = FALSE)
```

**Arguments**

X	a required numeric vector of training data lying in $[a, b]$
Y	an optional numeric vector of evaluation data lying in $[a, b]$
h	an optional bandwidth ( $>0$ )
a	an optional lower bound (defaults to lower bound of empirical support $\min(X)$ )
b	an optional upper bound (defaults to upper bound of empirical support $\max(X)$ )
bwmethod	whether to conduct bandwidth search via least squares cross-validation ("cv.ls") or likelihood cross-validation ("cv.ml")
cv	an optional argument for search (default is likely more reliable in the presence of local maxima)
grid	an optional grid used for the initial grid search when <code>cv="grid-hybrid"</code>
kertype	an optional kernel specification (defaults to "gaussian1")
nmulti	number of multi-starts used when <code>cv="numeric"</code> (defaults to 5)
proper	an optional logical value indicating whether to enforce proper density and distribution function estimates over the range $[a, b]$

**Details**

Typical usages are (see below for a complete list of options and also the examples at the end of this help file)

```
model <- npuniden.boundary(X, a=-2, b=3)
```

`npuniden.boundary` implements a variety of methods for estimating a univariate density function defined over a continuous random variable in the presence of bounds via the use of so-called boundary or edge kernel functions.

The kernel functions "beta1" and "beta2" are Chen's (1999) type 1 and 2 kernel functions with biases of  $O(h)$ , the "gamma" kernel function is from Chen (2000) with a bias of  $O(h)$ , "rigaussian"

is the reciprocal inverse Gaussian kernel function (Scaillet (2004), Igarashi & Kakizawa (2014)) with bias of  $O(h)$ , and "gaussian1" and "gaussian2" are truncated Gaussian kernel functions with biases of  $O(h)$  and  $O(h^2)$ , respectively. The kernel functions "fb", "fbl" and "fbu" are floating boundary polynomial biweight kernels with biases of  $O(h^2)$  (Scott (1992), Page 146). Without exception, these kernel functions are asymmetric in general with shape that changes depending on where the density is being estimated (i.e., how close the estimation point  $x$  in  $\hat{f}(x)$  is to a boundary). This function is written purely in R, so to see the exact form for each of these kernel functions, simply enter the name of this function in R (i.e., enter `npuniden.boundary` after loading this package) and scroll up for their definitions.

The kernel functions "gamma", "rigaussian", and "fbl" have support  $[a, \infty]$ . The kernel function "fbu" has support  $[-\infty, b]$ . The rest have support on  $[a, b]$ . Note that the two sided support default values are  $a=\min(X)$  and  $b=\max(X)$ .

Note that data-driven bandwidth selection is more nuanced in bounded settings, therefore it would be prudent to manually select a bandwidth that is, say,  $1/25$ th of the range of the data and manually inspect the estimate (say  $h=0.05$  when  $X \in [0, 1]$ ). Also, it may be wise to compare the density estimate with that from a histogram with the option `breaks=25`. Note also that the kernel functions "gaussian2", "fb", "fbl" and "fbu" can assume negative values leading to potentially negative density estimates, and must be trimmed when conducting likelihood cross-validation which can lead to oversmoothing. Least squares cross-validation is unaffected and appears to be more reliable in such instances hence is the default here.

Scott (1992, Page 149) writes "While boundary kernels can be very useful, there are potentially serious problems with real data. There are an infinite number of boundary kernels reflecting the spectrum of possible design constraints, and these kernels are not interchangeable. Severe artifacts can be introduced by any one of them in inappropriate situations. Very careful examination is required to avoid being victimized by the particular boundary kernel chosen. Artifacts can unfortunately be introduced by the choice of the support interval for the boundary kernel."

Note that since some kernel functions can assume negative values, this can lead to improper density estimates. The estimated distribution function is obtained via numerical integration of the estimated density function and may itself not be proper even when evaluated on the full range of the data  $[a, b]$ . Setting the option `proper=TRUE` will render the density and distribution estimates proper over the full range of the data, though this may not in general be a mean square error optimal strategy.

Finally, note that this function is pretty bare-bones relative to other functions in this package. For one, at this time there is no automatic print support so kindly see the examples for illustrations of its use, among other differences.

## Value

`npuniden.boundary` returns the following components:

<code>f</code>	estimated density at the points <code>X</code>
<code>F</code>	estimated distribution at the points <code>X</code> (numeric integral of <code>f</code> )
<code>sd.f</code>	asymptotic standard error of the estimated density at the points <code>X</code>
<code>sd.F</code>	asymptotic standard error of the estimated distribution at the points <code>X</code>
<code>h</code>	bandwidth used
<code>nmulti</code>	number of multi-starts used

**Description**

npuniden.reflect computes kernel univariate unconditional density estimates given a vector of continuously distributed training data and, optionally, a bandwidth (otherwise likelihood cross-validation is used for its selection). Lower and upper bounds  $[a,b]$  can be supplied (default is  $[0,1]$ ) and if  $a$  is set to  $-\text{Inf}$  there is only one bound on the right, while if  $b$  is set to  $\text{Inf}$  there is only one bound on the left.

**Usage**

```
npuniden.reflect(X = NULL,
                 Y = NULL,
                 h = NULL,
                 a = 0,
                 b = 1,
                 ...)
```

**Arguments**

X	a required numeric vector of training data lying in $[a, b]$
Y	an optional numeric vector of evaluation data lying in $[a, b]$
h	an optional bandwidth ( $>0$ )
a	an optional lower bound (defaults to 0)
b	an optional upper bound (defaults to 1)
...	optional arguments passed to npudensbw and npudens

**Details**

Typical usages are (see below for a complete list of options and also the examples at the end of this help file)

```
model <- npuniden.reflect(X,a=-2,b=3)
```

npuniden.reflect implements the data-reflection method for estimating a univariate density function defined over a continuous random variable in the presence of bounds.

Note that data-reflection imposes a zero derivative at the boundary, i.e.,  $f'(a) = f'(b) = 0$ .

**Value**

npuniden.reflect returns the following components:

f	estimated density at the points X
F	estimated distribution at the points X (numeric integral of f)
sd.f	asymptotic standard error of the estimated density at the points X
sd.F	asymptotic standard error of the estimated distribution at the points X
h	bandwidth used
nmulti	number of multi-starts used

---

*Kernel Shape Constrained Bounded Univariate Density Estimation*

---

## Description

npuniden.sc computes shape constrained kernel univariate unconditional density estimates given a vector of continuously distributed training data and a bandwidth. Lower and upper bounds [a,b] can be supplied (default is [0,1]) and if a is set to -Inf there is only one bound on the right, while if b is set to Inf there is only one bound on the left.

## Usage

```

npuniden.sc(X = NULL,
            Y = NULL,
            h = NULL,

```

```

a = 0,
b = 1,
lb = NULL,
ub = NULL,
extend.range = 0,
num.grid = 0,
function.distance = TRUE,
integral.equal = FALSE,
constraint = c("density",
               "mono.incr",
               "mono.decr",
               "concave",
               "convex",
               "log-concave",
               "log-convex"))

```

### Arguments

X	a required numeric vector of training data lying in $[a, b]$
Y	an optional numeric vector of evaluation data lying in $[a, b]$
h	a bandwidth ( $> 0$ )
a	an optional lower bound on the support of X or Y (defaults to 0)
b	an optional upper bound on the support of X or Y (defaults to 1)
lb	a scalar lower bound ( $\geq 0$ ) to be used in conjunction with <code>constraint="density"</code>
ub	a scalar upper bound ( $\geq 0$ and $\geq lb$ ) to be used in conjunction with <code>constraint="density"</code>
extend.range	number specifying the fraction by which the range of the training data should be extended for the additional grid points (passed to the function <code>extendrange</code> )
num.grid	number of additional grid points (in addition to X and Y) placed on an equi-spaced grid spanning <code>extendrange(c(X, Y), f=extend.range)</code> (if <code>num.grid=0</code> no additional grid points will be used regardless of the value of <code>extend.range</code> )
function.distance	a logical value that, if TRUE, minimizes the squared deviation between the constrained and unconstrained estimates, otherwise, minimizes the squared deviation between the constrained and unconstrained weights
integral.equal	a logical value, that, if TRUE, adjusts the constrained estimate to have the same probability mass over the range X, Y, and the additional grid points
constraint	a character string indicating whether the estimate is to be constrained to be monotonically increasing ( <code>constraint="mono.incr"</code> ), decreasing ( <code>constraint="mono.decr"</code> ), convex ( <code>constraint="convex"</code> ), concave ( <code>constraint="concave"</code> ), log-convex ( <code>constraint="log-convex"</code> ), or log-concave ( <code>constraint="log-concave"</code> )

### Details

Typical usages are (see below for a complete list of options and also the examples at the end of this help file)

```
model <- npuniden.sc(X,a=-2,b=3)
```

npuniden.sc implements a methods for estimating a univariate density function defined over a continuous random variable in the presence of bounds subject to a variety of shape constraints. The bounded estimates use the truncated Gaussian kernel function.

Note that for the log-constrained estimates, the derivative estimate returned is that for the log-constrained estimate not the non-log value of the estimate returned by the function. See Example 5 below that manually plots the log-density and returned derivative (no transformation is needed when plotting the density estimate itself).

If the quadratic program solver fails to find a solution, the unconstrained estimate is returned with an immediate warning. Possible causes to be investigated are undersmoothing, sparsity, and the presence of non-sample grid points. To investigate the possibility of undersmoothing try using a larger bandwidth, to investigate sparsity try decreasing `extend.range`, and to investigate non-sample grid points try setting `num.grid` to 0.

Mean square error performance seems to improve generally when using additional grid points in the empirical support of  $X$  and  $Y$  (i.e., in the observed range of the data sample) but appears to deteriorate when imposing constraints beyond the empirical support (i.e., when `extend.range` is positive). Increasing the number of additional points beyond a hundred or so appears to have a limited impact.

The option `function.distance=TRUE` appears to perform better for imposing convexity, concavity, log-convexity and log-concavity, while `function.distance=FALSE` appears to perform better for imposing monotonicity, whether increasing or decreasing (based on simulations for the Beta( $s_1, s_2$ ) distribution with sample size  $n = 100$ ).

## Value

A list with the following elements:

<code>f</code>	unconstrained density estimate
<code>f.sc</code>	shape constrained density estimate
<code>se.f</code>	asymptotic standard error of the unconstrained density estimate
<code>se.f.sc</code>	asymptotic standard error of the shape constrained density estimate
<code>f.deriv</code>	unconstrained derivative estimate (of order 1 or 2 or log thereof)
<code>f.sc.deriv</code>	shape constrained derivative estimate (of order 1 or 2 or log thereof)
<code>F</code>	unconstrained distribution estimate
<code>F.sc</code>	shape constrained distribution estimate
<code>integral.f</code>	the integral of the unconstrained estimate over $X$ , $Y$ , and the additional grid points
<code>integral.f.sc</code>	the integral of the constrained estimate over $X$ , $Y$ , and the additional grid points
<code>solve.QP</code>	logical, if <code>TRUE</code> <code>solve.QP</code> succeeded, otherwise failed
<code>attempts</code>	number of attempts when <code>solve.QP</code> fails (max = 9)

## End(Not run)

```

---

npunitest	<i>Kernel Consistent Univariate Density Equality Test with Mixed Data Types</i>
-----------	---

---

## Description

npunitest implements the consistent metric entropy test of Maasoumi and Racine (2002) for two arbitrary, stationary univariate nonparametric densities on common support.

## Usage

```

npunitest(data.x = NULL,
          data.y = NULL,
          method = c("integration","summation"),
          bootstrap = TRUE,
          boot.num = 399,
          bw.x = NULL,

```

```

    bw.y = NULL,
    random.seed = 42,
    ...)

```

### Arguments

<code>data.x, data.y</code>	common support univariate vectors containing the variables.
<code>method</code>	a character string used to specify whether to compute the integral version or the summation version of the statistic. Can be set as <code>integration</code> or <code>summation</code> . Defaults to <code>integration</code> . See ‘Details’ below for important information regarding the use of summation when <code>data.x</code> and <code>data.y</code> lack common support and/or are sparse.
<code>bootstrap</code>	a logical value which specifies whether to conduct the bootstrap test or not. If set to <code>FALSE</code> , only the statistic will be computed. Defaults to <code>TRUE</code> .
<code>boot.num</code>	an integer value specifying the number of bootstrap replications to use. Defaults to 399.
<code>bw.x, bw.y</code>	numeric (scalar) bandwidths. Defaults to plug-in (see details below).
<code>random.seed</code>	an integer used to seed R’s random number generator. This is to ensure replicability. Defaults to 42.
<code>...</code>	additional arguments supplied to specify the bandwidth type, kernel types, and so on. This is used since we specify <code>bw</code> as a numeric scalar and not a bandwidth object, and is of interest if you do not desire the default behaviours. To change the defaults, you may specify any of <code>bwscaling</code> , <code>bwtype</code> , <code>ckertype</code> , <code>ckerorder</code> , <code>ukertype</code> , <code>okertype</code> .

### Details

`npunittest` computes the nonparametric metric entropy (normalized Hellinger of Granger, Maasoumi and Racine (2004)) for testing equality of two univariate density/probability functions,  $D[f(x), f(y)]$ . See Maasoumi and Racine (2002) for details. Default bandwidths are of the plug-in variety ([bw.SJ](#) for continuous variables and direct plug-in for discrete variables). The bootstrap is conducted via simple resampling with replacement from the pooled `data.x` and `data.y` (`data.x` only for summation).

The summation version of this statistic can be numerically unstable when `data.x` and `data.y` lack common support or when the overlap is sparse (the summation version involves division of densities while the integration version involves differences, and the statistic in such cases can be reported as exactly 0.5 or 0). Warning messages are produced when this occurs (‘integration recommended’) and should be heeded.

Numerical integration can occasionally fail when the `data.x` and `data.y` distributions lack common support and/or lie an extremely large distance from one another (the statistic in such cases will be reported as exactly 0.5 or 0). However, in these extreme cases, simple tests will reveal the obvious differences in the distributions and entropy-based tests for equality will be clearly unnecessary.

### Value

`npunittest` returns an object of type `unitest` with the following components

**Srho**                    the statistic **Srho**  
**Srho.bootstrap**       contains the bootstrap replications of **Srho**  
**P**                        the P-value of the statistic  
**boot.num**               number of bootstrap replications  
**bw.x, bw.y**             scalar bandwidths for **data.x**, **data.y**

[summary](#) supports object of type `unitest`.

oecdpanel

*Cross Country Growth Panel*

## Description

Cross country GDP growth panel covering the period 1960-1995 used by Liu and Stengos (2000) and Maasoumi, Racine, and Stengos (2007). There are 616 observations in total. `data("oecdpanel")` makes available the dataset "oecdpanel" plus an additional object "bw".

## Usage

```
data("oecdpanel")
```

## Format

A data frame with 7 columns, and 616 rows. This panel covers 7 5-year periods: 1960-1964, 1965-1969, 1970-1974, 1975-1979, 1980-1984, 1985-1989 and 1990-1994.

A separate local-linear rbandwidth object (bw) has been computed for the user's convenience which can be used to visualize this dataset using `plot(bw)`.

**growth** the first column, of type numeric: growth rate of real GDP per capita for each 5-year period

**oecd** the second column, of type factor: equal to 1 for OECD members, 0 otherwise

**year** the third column, of type integer

**initgdp** the fourth column, of type numeric: per capita real GDP at the beginning of each 5-year period

**popgro** the fifth column, of type numeric: average annual population growth rate for each 5-year period

**inv** the sixth column, of type numeric: average investment/GDP ratio for each 5-year period

**humancap** the seventh column, of type numeric: average secondary school enrolment rate for each 5-year period

---

se

---

*Extract Standard Errors*

---

**Description**

se is a generic function which extracts standard errors from objects.

**Usage**

```
se(x)
```

**Arguments**

x                      an object for which the extraction of standard errors is meaningful.

**Details**

This function provides a generic interface for extraction of standard errors from objects.

**Value**

Standard errors extracted from the model object x.

**Note**

This method currently only supports objects from the [np](#) library.

**Author(s)**

Tristen Hayfield <tristen.hayfield@gmail.com>, Jeffrey S. Racine <racinej@mcmaster.ca>

**See Also**

[fitted](#), [residuals](#), [coef](#), and [gradients](#), for related methods; [np](#) for supported objects.

**Examples**

```
x <- rnorm(10)
se(npudens(npudensbw(~x)))
```

---

uocquantile

*Compute Quantiles*

---

**Description**

uocquantile is a function which computes quantiles of an unordered, ordered or continuous variable *x*.

**Usage**

```
uocquantile(x, prob)
```

**Arguments**

<i>x</i>	an ordered, unordered or continuous variable.
<i>prob</i>	quantile to compute.

**Details**

uocquantile is a function which computes quantiles of an unordered, ordered or continuous variable *x*. If *x* is unordered, the mode is returned. If *x* is ordered, the level for which the cumulative distribution is  $\geq$  *prob* is returned. If *x* is continuous, [quantile](#) is invoked and the result returned.

**Value**

A quantile computed from *x*.

**Author(s)**

Tristen Hayfield <tristen.hayfield@gmail.com>, Jeffrey S. Racine <racinej@mcmaster.ca>

**See Also**

[quantile](#)

**Examples**

```
x <- rbinom(n = 100, size = 10, prob = 0.5)
uocquantile(x, 0.5)
```

wage1

*Cross-Sectional Data on Wages***Description**

Cross-section wage data consisting of a random sample taken from the U.S. Current Population Survey for the year 1976. There are 526 observations in total. `data("wage1")` makes available the dataset "wage" plus additional objects "bw.all" and "bw.subset".

**Usage**

```
data("wage1")
```

**Format**

A data frame with 24 columns, and 526 rows.

Two local-linear rbandwidth objects (bw.all and bw.subset) have been computed for the user's convenience which can be used to visualize this dataset using `plot(bw.all)`

**wage** column 1, of type numeric, average hourly earnings

**educ** column 2, of type numeric, years of education

**exper** column 3, of type numeric, years potential experience

**tenure** column 4, of type numeric, years with current employer

**nonwhite** column 5, of type factor, ="Nonwhite" if nonwhite, "White" otherwise

**female** column 6, of type factor, ="Female" if female, "Male" otherwise

**married** column 7, of type factor, ="Married" if Married, "Nonmarried" otherwise

**numdep** column 8, of type numeric, number of dependants

**smsa** column 9, of type numeric, =1 if live in SMSA

**northcen** column 10, of type numeric, =1 if live in north central U.S

**south** column 11, of type numeric, =1 if live in southern region

**west** column 12, of type numeric, =1 if live in western region

**construc** column 13, of type numeric, =1 if work in construction industry

**ndurman** column 14, of type numeric, =1 if in non-durable manufacturing industry

**trcommptu** column 15, of type numeric, =1 if in transportation, communications, public utility

**trade** column 16, of type numeric, =1 if in wholesale or retail

**services** column 17, of type numeric, =1 if in services industry

**profserv** column 18, of type numeric, =1 if in professional services industry

**profocc** column 19, of type numeric, =1 if in professional occupation

**clerocc** column 20, of type numeric, =1 if in clerical occupation

**servocc** column 21, of type numeric, =1 if in service occupation

**lwage** column 22, of type numeric,  $\log(\text{wage})$

**expersq** column 23, of type numeric,  $\text{exper}^2$

**tenursq** column 24, of type numeric,  $\text{tenure}^2$
